was read by Mr. C. G. SIMPSON, D.Sc., Director of the Meteorological Office. He said that whatever might be the opinion of medical men on the interaction between the weather and personal health, the ideas of the man-in-the-street were very hazy, and he would approach the subject from the latter's standpoint. Ordinary people had heard of such factors as *atmospheric electricity, ozone, radioactivity,* and ultra-violet light, and there was a tendency to ascribe to all and each of them happenings which seemed otherwise obscure. The inquirer should be on his guard concerning this tendency to explain the unfamiliar by the familiar. It was the common custom to pick out coincidences and attribute to them the exaggerated importance of cause and effect. In all such inquiries it was necessary to have the mathematical coefficient, and records must be made at regular intervals, and, if possible, by independent observers. It had always been the custom to associate bad smells with illness, pleasant odours with good health, and this became a danger when the carrying of flowers and perfume boxes was a recognised method of keeping away infection. In assessing the influence of weather on health it was important to separate the physical effect from the psychological. People believed it was unhealthy to sit in a room with closed windows, that the shutting of the windows deprived the contained air of some of its virtue; but in most rooms in this country enough air exchange was effected to obviate any ill-effects. The depression felt by people sitting in a closed room was, Dr. Simpson contended, chiefly psychological. And the ordinary barometric pressure changes could have no detrimental effect on health; certainly they were too gradual for this to happen. An ascent to high altitudes rapidly in an aeroplane, or the quick descent into a coal-mine was a different proposition largely because of the different proportion of oxygen present in the air.

Temperature changes were important, but largely because we objected to the discomfort of feeling very cold or very hot. It was astonishing what changes in temperature the body would tolerate without ill-effects, always providing the air was calm. One night while he was in the Antartic regions he was called out of bed to look at a display of the aurora Clad only lightly he went outside and remained there over an hour with the temperature at 90° (frost, without coming to any harm. It was a ver calm night, so that the loss of heat from the bod was at the minimum for the temperature. In suc intense cold, however, one would be unable to wal quickly or run, for the intake of air produced acu pain in the throat and bronchi.

With regard to humidity, the air breathed o contained water up to saturation point for t temperature; in the air inspired the proportı of water vapour varied with the weather conditior If the air was very dry, breathing produced a gradual increasing thirst, owing to the drainage of water fro the system. This was the explanation of the gre thirst experienced by Polar explorers, which w easily remedied by taking in a certain quantity snow. The higher the relative humidity of t air, the less the evaporation from the body. It w not true to say that when the air was very humid the was no evaporation taking place from the bod because—in this country at least—the body w always warmer than the surrounding air. I determining the degree of unhealthiness of a clim he commended the wet-bulb thermometer. Wh in India, it was estimated that the wet-bulb thern meter would rise to 80°, telegrams were sent to t different cantonments concerned, and exercises a all extra work by the troops were stopped or curtail

In Dr. Simpson's view, the only important influe which weather had on the body was its extraction heat from the body; and when the quantity extracted was reasonable, the sensation was one stimulation. The invigorating effect felt on pass from a closed room into a brisk wind was not due a different composition of the air in the two places, l to the air in motion extracting heat from the bc rapidly. The question had been many times discus as to why two seaside towns on the same coast sho bear a different reputation. The difference wo usually be found to be solely due to the more brac town having its promenade right on the sea-fro with nothing to obstruct the wind, while the oth not far away, was largely protected from the la ward winds, either by the conformation of the land because the beach for visitors was some dista back. The merits of seaside places could not ascribed to ozone; Lord Rayleigh had declared t the quantity in the air was so minute that e the most delicate instruments scarcely recor any; it was declared to be 3 mg. to 100 kg. of and that was equalled by many industrial towns

Fogs were generally supposed to be unhealt but if a fog was clean he did not see why it should be breathed without detriment, for the composit of the air was then no different. It might, course, have a depressing mental effect. Dirty f were an entirely different matter, for the pollut conveyed to the air was held in suspension by it, a was breathed into the lungs. People put do wonderful things to radiation, but he sugges that there were only three ways in which it co affect the human body: thermally, chemically, a psychologically. Whether they were long wa as in wireless reception, or short waves, like those ultra-violet light, their characteristic was that w absorbed they produced heat. Visible rays w absorbed by different bodies according to their colo a black body absorbed all the visible rays, a white b reflected all, while other colours were intermedi esent. Whatever may be the explanation the idence to incriminate the sand-fly is so overwhelming, id Dr. Wenyon, that investigations may be continued ith confidence that ultimately the missing factor ill be discovered and the sand-fly theory of transission of kala-azar and oriental sore will receive mplete justification.

CHELSEA CLINICAL SOCIETY.

Dr. H. Rivers Pollock, the President, took the hair at a meeting of this society held on Jan. 19th t the Hotel Rembrandt, and Mr. Guy C. Pollock Managing Editor of the *Morning Post*) opened a discussion on

Medicine and the Press.

He complained that, while the medical profession claimed to abhor advertisement, it advertised in many ways, such as the exhibition of plates, the compilation of lists of names and qualifications, and the publication of bulletins on the health of celebrities. He felt that the position was ridiculous. The journalist who wanted to publish medical information acceptable to his public must have a signed article; he might induce a big man to defy the General Medical Council, but if he could not, then he had to have his article written by a layman under the guise of "A Harley-street Specialist," or by an insignificant medical man who thought the risk worth taking in order to curry favour with the public. The public was always extremely interested in its health and wanted to know about new diseases and about really serious things like epidemics; it ought to have access to the opinions of properly qualified persons whose worth it could judge from their signatures. The public much preferred the signature of a nonentity to no signature at all. For this reason no newspaper liked the idea of receiving its news from a committee of experts, as suggested by some reformers; moreover, it did not want matter which was being distributed to competitors. He claimed for the *Morning Post* and for Mr. Gwynne, its editor, some recognition of the courage shown in being the first to deal frankly, at the request of the leaders of the medical profession, with the problems of venereal disease.

Sir Squire Sprigge (Editor of *The Lancet*) first dealt shortly with articles on public medicine—the administration of the health laws, the management of public medical institutions, vital statistics and similar matters—for which he held that no signature was required, as all the facts could be verified. Indeed, many of such articles could properly be signed. Though articles of this kind were often written in a dull way, there was no reason why they should not be made readable, and their potential educative value was very great. He then admitted that the public wanted the "story" of the general treatment and of the new medical discovery, and to have this story signed, preferably by an eminent authority, but in default by anybody. The General Medical Council had made no rule against signing articles but had expressed a strong adverse opinion in certain directions. and had done so for two reasons: first, no individual view on treatment was worth anything as a general guide; and secondly, the doctor who signed an article on treatment knew for that reason that his views were untrustworthy. The medical profession therefore felt that such a man was certainly pretentious and in all probability would attract to himself the patients of other doctors; he wronged the profession and the public alike. Moreover, he inspired false hopes in the untreated and caused disappointment to those who had been treated in other ways, thus sapping the confidence of the public in the profession.

The speaker suggested tentatively that newspapers might find it very useful to provide themselves with medical "advisers," as distinguished from correspondents. An adviser might never write a word, but would give the editor informed and intimate criticism of medical articles. The leaders of the profession would be perfectly willing to coöperate in this way, provided that they were not hurried. The trouble was that, no matter how important a subject might be, speed of publication was regarded as the first essential, and questions concerning medical matters could not be satisfactorily answered without time and care. Nevertheless, if only editors could arrange for an answer to the simple questions: "Is this old? new? sound? probable? informed? disinterested?" half their difficulties would be over. If medical information were put on that basis of serious responsibility, signatures would not be required; the articles would be signed by the prestige of the paper.

DISCUSSION.

Mr. Philip Page, a colleague at one time of Mr. Pollock, held that journalism being already overrun with blacklegs, it was a most blessed thing that Harley-street was content to save humanity and to refrain from teaching humanity on paper.

Dr. Ernest Young deplored the practice of some editors of communicating the names of anonymous and pretentious medical authors to persons who wrote asking for them. In this way a writer might gain far more illegitimate advantage from an unsigned than from a signed article.

Mr. Ivor Back agreed with all the views of Mr. Pollock. None of his audience, he said, would linger over unsigned articles entitled "Is there a God?" or "Is Death by Hanging Instantaneous?" but if those articles were signed respectively by Dean Inge or Mr. Pierpoint, they would be read with enthusiasm. Moreover, if articles were signed, the public would soon find out which authors were valuable and which were worthless.

Dr. Scott Stevenson (Editor of the *Practitioner*) denied that articles would not be read unless they were signed. He was more interested in the leading articles of *The Lancet* than in the original signed communications. In his early days he had contributed many articles on medicine to the lay press, although he had never signed one; if an article could not get in on its own merits, it would not get in whatever name were appended to it. The good newspaper article was one that was readable and topical.

Dr. K. Eckenstein said that most medical articles in the public press consisted of medical "discoveries," and that the great thing from the journalistic point of view was news.

Dr. C. F. Beevor expressed weariness with pseudo-advertising, and advocated the establishment of a committee to be responsible, in all but the leading newspapers, for medical articles and the bulletins of celebrities.

Mr. Herbert Tilley inquired where, if Mr. Pollock once admitted the signing of articles, he would draw the limiting line for that form of advertising. At present there was one law for the G.P.

close intimacy with infected animals, this contaminative method of infection directly from man to man can hardly occur on a large scale in nature. The organism is not sufficiently resistant, while the flagellate stage is unaccounted for. Again, though the Leishman-Donovan body will develop into a flagellate in the stomach of the bed-bug and will survive for as long as five or six weeks, there is no active multiplication while the three conditions mentioned above are not fulfilled. Moreover there is no correlation between the distribution of kala-azar and oriental sore and bed-bugs. It seems clear that the stomach of the bed-bug is acting merely as an imperfect culture tube and that the development of the Leishman-Donovan body is an abortive one.

The flea at one time was suspect but attempts at transmission by this insect as also with the bed-bug have failed entirely. Similar experiments with other blood-sucking invertebrates have shown that though the parasites may survive in the intestine for some time no development occurs. The sand-fly alone appears to answer all requirements except that of actual experimental transmission. Both kala-azar and oriental sore occur only in districts where these insects are found, though there are places where sand-flies abound in which these diseases are unknown. Nevertheless certain species in their distribution correspond closely with the endemic centres. Thus in India *P. argentipes* is closely associated with kala-azar, and this is true of *P. major* var. *chinensis* and *P. perniciosus* in the North China and the Mediterranean regions respectively. In the case of oriental sore *P. papatasii* and *P. sergenti* can similarly be suspected. If these sand-flies are fed on cases of the diseases in man or experimental animals the parasites ingested undergo a remarkable change. There is a rapid development of the flagellate stage followed by active multiplication till the whole of the midgut is a seething mass of organisms which in the neighbourhood of the proventriculus are attached to the epithelial lining. The infection spreads forwards along the œsophagus to the pharynx and even into the proboscis itself. A condition is produced like that seen in plague-infected fleas in which these regions of the alimentary tract are blocked with plague bacilli. It has been demonstrated by Adler and Theodor that if infected sand-flies are allowed to feed through a membrane on sterile fluid, flagellates can be found in the fluid afterwards, a fact which proves conclusively that flagellates are discharged from the proboscis during the feeding act. Furthermore, it has been demonstrated that the flagellates in the sand-flies are virulent and will produce oriental sore or kala-azar if injected into experimental animals. It is almost impossible to suppose that the whole of this remarkable development is accidental and has no bearing on the ætiology of the diseases.

The complete development as described above does not occur in all sand-flies. There is evidence that for each locality there is the right sand-fly and the right strain of parasite. In India it is the local strain of *Leishmania donovani* and *Phlebotomus argentipes*, in North China the Chinese *L. donovani* and *P. major* var. *chinensis*, in Sicily and Malta *L. infantum* and *P. perniciosus*, in Palestine *L. tropica* and *P. papatasii*, and in Bagdad *L. tropica* and *P. sergenti*. The local strains will develop to some extent in other sand-flies but less completely and with a lower rate of infections. Under favourable conditions when there is opportunity for every sand-fly fed to take up parasites the infection-rate in the species mentioned may approach 100 per cent. This occurs in cases of kala-azar in dogs or experimental hamsters when there is a heavy infection of the skin with *L. donovani* ensuring that every sand-fly has ingested parasites. Apart from the evidence supplied by experiments with the human strains of leishmania certain work with leishmania infections of lizards is very suggestive. Geckos, on which certain species of sand-fly feed almost exclusively, are liable to harbour parasites allied to those of kala-azar and oriental sore. It has been shown in certain cases that the sand-flies become infected by feeding on the geckos but the development occurs in the hind-gut and not in the anterior part of the alimentary canal. It is highly probable that the geckos acquire their infection by devouring infected sand-flies. These observations again indicate a specific relationship between sand-flies and the vertebrate parasites of the leptomonas type.

Though from the data given above it would seem that there was every reason to suppose that sand-flies were the vectors of kala-azar and oriental sore, the final proof of experimental transmission by the bite has been more difficult of realisation than was expected. In the various centres where investigations have been carried on, thousands of infected sand-flies have been fed on human beings or susceptible animals such as the hamster without infection occurring. The extent of the work is well illustrated by the figures given in 1928 by Shortt, head of the Kala-Azar Commission in Assam. In all 273,467 sand-flies have been bred in the laboratory and of these 79,939 were actually fed. Of sand-flies, a large proportion of which were known to be infected, 3590 were fed on white mice, 2325 on the Chinese hamster, and 1247 on human volunteers. Similar though smaller figures appear from the records of work at other centres. In spite of this, experimental transmission was not effected. Nevertheless the work was still continued with the result that from Assam has recently come the report of the successful infection of one hamster by the bite of *P. argentipes*. On this animal there were fed during the course of 17 months 12 dozen *P. argentipes*, the majority of which must have been infected. Previously Adler and Theodor in Palestine had fed on the arm of a volunteer a number of *P. papatasii* infected with *Leishmania tropica*. As in six months no infection had appeared the volunteer was inoculated on the other arm for another purpose. Some months later lesions appeared at the exact spot on which the sand-flies had originally fed, and in these parasites were demonstrated. The man had lived in a part of Jerusalem where imported cases of oriental sore occurred, so that there was a possibility of his acquiring infection there. Nevertheless the appearance of lesions at the actual spot on which the sand-flies had fed is very suggestive that experimental transmission had been effected. Chodukin and his assistants working in Taschkent report that they have transmitted oriental sore from dog to dog. A dog with oriental sore was placed in a fly-proof cage and kept at one end while at the other end were four healthy puppies. Sand-flies were constantly introduced during three months. Two months later one of the puppies was found to have oriental sore. These are the only instances in which there is any possibility that kala-azar and oriental sore have been transmitted by the bite of the sand-fly. It seems evident that there is some missing factor. Knowles has suggested that in Bengal there may be wholesale inoculation of the population and that kala-azar only results when this factor, which may be a depression due to typhoid fever or malaria, is

REVIEWS AND NOTICES OF BOOKS

Index of Prognosis

And End-Results of Treatment. Fourth edition. By Various Authors. Edited by A. RENDLE SHORT, M.D., F.R.C.S., Hon. Surgeon, Bristol Royal Infirmary. Bristol: John Wright and Sons, Ltd. 1932. Pp. 599. 42*s*.

FEW subjects offer greater difficulty to physician surgeon than that of prognosis; upon no subject it more difficult to be precise. The individual riations in constitution, heredity, age, and the like 'er so many problems that the outcome of similar ions in different individuals can rarely be proesied. Mass statistics and "average" figures provide certain guides. At the same time a consideration all the factors in a given case viewed in the light the collected statistics of many hundreds of cases ould give some insight into the end-results of eatment or the course of pathological processes. his book is more than a mere series of tables and gures with lists of insurance companies' statistics mortality-rates or expectation of life. It is a alanced and judicial account of the main points hich must be considered collectively before an pinion is formed as to prognosis. The distinguished st of authors has been increased in this edition by 3 new contributors, and much new work has been ncorporated. It is satisfactory to notice that in the ine years since the last edition was published the rognosis in such conditions as diabetes, cancer, eneral paralysis, pernicious anæmia, amœbic dysenery, among other diseases, has greatly improved. The most recent statistics are included, and many older ones are necessarily viewed in a new light. It s exceedingly important that vague generalisations about the results of treatment should as far as possible be replaced by definite information. Those who have not previously studied an index of prognosis will almost certainly be astonished at the verdict in connexion with diseases. A nebulous idea that on the whole patients "do well" or "die young" is often quite at variance with ascertained facts.

This book should be in the possession of every practitioner. It will prove a valuable friend, and if he remembers that percentages and statistics represent average findings and not any individual case he will not be betrayed by his reliance on the cumulative experience here recorded.

Handbook of Sanitary Law.

Eleventh edition. By B. BURNETT HAM, M.D., D.P.H. Camb. London: H. K. Lewis and Co. 1931. Pp. 336. 7*s*. 6*d*.

IN its new edition, Dr. Burnett Ham's Handbook of Sanitary Law continues to compress a marvellous store of information within a small compass. Intended for the use of candidates for public health qualifications, it may well also (as its author hopes) serve medical officers of health as a convenient work of reference. When first produced in 1899, its preface complained of the complicated condition of the Public Health Acts and similar statutes. The state of the law is now far worse. Even if the subject of housing was tidied up in 1925, section 63 (i) of the Housing Act of 1930 is a good instance of an alteration which can have a devastating effect upon exposition. Dr. Burnett Ham attacks these difficulties with success. The year named for the compulsory notification of tuberculosis on p. 209 ought, perhaps, to be 1912 instead of 1913; and the summary of cholera and plague precautions and of port sanitary duties might perhaps mention the curiously christened Public Health (Deratisation of Ships) Regulations of 1929. But a close examination of the Handbook makes a critic diffident of offering corrections however small or of discovering omissions. The author will probably turn out to be right, and the supposed omissions may in fact be included somewhere or other in this multum in parvo.

Matas Birthday Volume.

A Collection of Surgical Essays written in honour of Rudolph Matas, New Orleans. New York: Paul B. Hoeber Inc. 1931. Pp. 396. $10.00.

A SERIES of surgical essays has been published in honour of the seventieth birthday of Rudolph Matas by a group of his friends and former pupils. The first contribution is an admirable account by Dr. Mont R. Reid, of Cincinnati, of a group of cases of vascular lesions illustrating some of the principles taught by Prof. Matas. He describes the remarkable recovery of a bedridden invalid following the extirpation of a femoral arterio-venous aneurysm. This patient had been regarded as suffering from cirrhosis of the liver, and his ascites had been controlled by frequent paracentesis. Dr. Reid's paper is followed by a report on cases of Raynaud's disease and thrombo-angiitis obliterans of the upper limbs treated by ramisection by Prof. Alessandri, of Rome. The section on vascular surgery, to which Matas has made so many brilliant contributions, is completed by a paper on personal experiences in vascular surgery by Dr. Hubert A. Royster. Dr. Bloodgood, of Baltimore, contributes a biographical sketch of the late Prof. Halsted, entitled "Halsted Thirty-six Years Ago," while Dr. J. M. T. Finney and Dr. J. M. T. Finney, jun., describe a case of hypertrophic tuberculosis of the ileum, to which they append a full bibliography. Dr. Robert C. Coffey, of Portland, supplies a well-illustrated article on cancer of the rectum, which is quite outstanding in a galaxy of admirable essays. In it he describes his modification of the abdomino-perineal operation and gives statistics of his own cases. Dr. E. Ribas y Ribas, of Barcelona, reports a case of intestinal obstruction due to an obscure developmental anomaly in which the whole of the small intestine was removed, the patient surviving for six months. In an interesting study of cancer in the North American negro, Dr. Frederick L. Hoffman shows that the cancer death-rate has shown a persistent rise during the last thirty years, and now tends to approximate to that of the white population. J. Shelton Horsley and John B. Deaver write on cancer of the stomach and breast respectively, and Dr. George W. Crile contributes one of his typically stimulating articles on anæsthesia. Articles on rhinoplasty by Dr. Paul Moure, of Paris, on fistulas following hydatid cysts by Dr. Trias Pujol, of Barcelona, and on the place of the senses in the development of science by Dr. W. J. Mayo follow. Prof. D. P. D. Wilkie is the sole British contributor with an essay on splenectomy, and it would be hard to better his description of the operation, which is very and another for the J.P.: the hard-working general practitioner in a country village who wrote an article in the local press on his own observations on influenza would be attacked by all his colleagues, but a medical knight who wrote an article for the *Times* was handsomely rewarded. If a medical man could sign an article, why could he not have his name on a tin of patent food?

Mr. FRANK COKE remarked that, whereas workers in the large laboratories who made discoveries had an immediate entrée to the lay press, an obscure, lonely worker who made a discovery could only describe it in a medical paper and might fail to gain a hearing even there. The lay press was the only medium by which the news of a discovery reached the patient. All discoveries needed commercial interests to develop them; the obscure man who attempted to develop his discovery commercially was at once accused of selfishness or of having a secret remedy. The speaker advocated the establishment of a board for the purpose of furthering discoveries by obscure workers.

REPLIES.

Mr. POLLOCK retorted to Mr. Tilley that the thin end of the wedge had already been inserted in the shape of pseudo-advertising. He wished to draw no line; the G.M.C., the B.M.A., and many other influences were sufficient to keep advertising within reasonable bounds. He suggested that Dr. Stevenson's unsigned articles had been contributed some years ago and that he would not be so fortunate nowadays. He reiterated that an unsigned article had no commercial value. He brushed aside any idea of a "Lausanne Conference" in the shape of a board or committee, and emphasised the essentially ephemeral nature of newspaper articles.

Sir SQUIRE SPRIGGE agreed that the idea of a board or committee was futile. He assured Mr. Coke that the lonely, obscure research worker was a phantasm. Medical discoveries were almost without exception the result of previous work, founded on work previous to that; the fruit of a long series of triumphs and failures. By the time a real discovery was made, about ten persons could lay reasonable claim to having had something to do with it. He doubted whether, by bidding the unknown and lonely discoverer to go away, any injustice had ever been done.

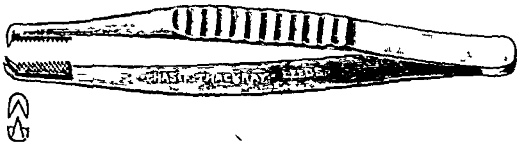
COLSTON RESEARCH SOCIETY, BRISTOL.

This society was founded over 30 years ago, as the University College Colston Society, to assist the Bristol University College financially, and to foster the idea of a University of Bristol. When at the end of ten years the University came into existence the society decided to devote itself to the encouragement of research in the University. A collection is made each year among the citizens of Bristol by the president, who is elected for one year only, and many thousands of pounds have been raised and used for this purpose. In the last few years the collection has averaged about £800. In 1931 Mr. Falk, the president, received a special gift of £5000 from eight donors for research in medicine, and it has been decided to apply the income of this fund to the provision of one or more Colston Medical Research Fellowships of not less than £100 per annum each, which shall be awarded by the Council of the society. They are intended primarily for clinical work, though other medical subjects are not excluded, and they will be open to any member of the medical profession in Bristol, preference being given to graduates or members of the teaching staff of the University. The work must be carried out in the University itself, or in one of the clinical institutions associated with it, and the Fellowships will be renewable yearly at discretion. Applications should reach the hon. secretary of the society, 12, Small-street, Bristol, on or before April 30th of each year.

NEW INVENTIONS

COMBINED TOOTHED DISSECTING AND SUTURE-HOLDING FORCEPS.

THE forceps here illustrated is designed for use as an ordinary toothed dissecting forceps, as well as for holding and keeping suture material taut during a continuous stitch, and in tying knots. The suture material may be readily grasped and held firmly between the evenly approximating surfaces without damage.

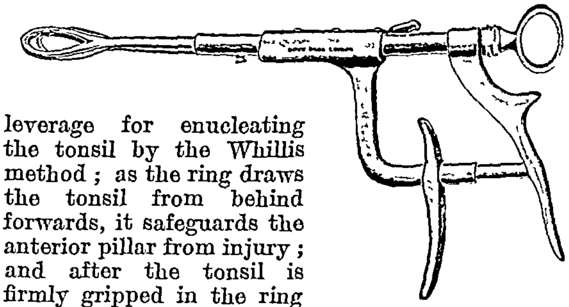


The instrument has been made for me by Chas. F. Thackray, Regent-street, London, W.

LANCELOT BROMLEY, M.Ch., F.R.C.S.

A MODIFIED FAHNESTOCK TONSIL ÉCRASEUR.

I HAVE been using a modification of Fahnestock's tonsil écraseur which has a double handle, thus affording a squeezing action. The advantages of this instrument (here illustrated) are: it gives good leverage for enucleating the tonsil by the Whillis method; as the ring draws the tonsil from behind forwards, it safeguards the anterior pillar from injury; and after the tonsil is firmly gripped in the ring by squeezing the handle, the process is continued by bringing the screw into action. By slowly rotating the ring the base of the tonsil is strangled and separated; if five minutes are allowed for each tonsil, the separation is practically bloodless and causes a minimum amount of trauma. The drawbacks are that the instrument is not suitable for rapid tonsillectomy with ethyl chloride; and it requires a prominent tonsil. For a flat tonsil, I prefer the Jenkin's guillotine.



Messrs. Down Bros., St. Thomas's-street, London, S.E., have carried out my design of this instrument.

T. B. JOBSON, M.D.

INFLUENZA IN A HOSPITAL.—Owing to influenza among the staff, Barnet Cottage Hospital, Herts, has had to refuse new patients. Seventeen inmates have been removed elsewhere; the 13 that remain cannot safely be removed. One of the maids has died, and it is reported that the matron, the sister-in-charge, two probationer nurses, two ward-maids, and another maid are ill.

REVIEWS AND NOTICES OF BOOKS

Dr. Bloodgood, of Baltimore, contributes a biographical sketch of the late Prof. Halsted, entitled "Halsted Thirty-six Years Ago," while Dr. J. M. T. Finney and Dr. J. M. T. Finney, jun., describe a case of hypertrophic tuberculosis of the ileum, to which they append a full bibliography. Dr. Robert C. Coffey, of Portland, supplies a well-illustrated article on cancer of the rectum, which is quite outstanding in a galaxy of admirable essays. In it he describes his modification of the abdomino-perineal operation and gives statistics of his own cases. Dr. E. Ribas y Ribas, of Barcelona, reports a case of intestinal obstruction due to an obscure developmental anomaly in which the whole of the small intestine was removed, the patient surviving for six months. In an interesting study of cancer in the North American negro, Dr. Frederick L. Hoffman shows that the cancer death-rate has shown a persistent rise during the last thirty years, and now tends to approximate to that of the white population. J. Shelton Horsley and John B. Deaver write on cancer of the stomach and breast respectively, and Dr. George W. Crile contributes one of his typically stimulating articles on anæsthesia. Articles on rhinoplasty by Dr. Paul Moure, of Paris, on fistulas following hydatid cysts by Dr. Trias Pujol, of Barcelona, and on the place of the senses in the development of science by Dr. W. J. Mayo follow. Prof. D. P. D. Wilkie is the sole British contributor with an essay on splenectomy, and it would be hard to better his description of the operation, which is very well illustrated, and his accounts of treated cases. The last essay in the book is by Dr. Howard Lilienthal on the Operative Treatment of Phthisis, in which he makes a powerful plea to surgeons not to withhold their help from the desperate case, illustrating his thesis with ten case reports. The plea is particularly appropriate in this book, because for many years past advanced cases of vascular disease have been referred to Matas from all over America, and very seldom has he refused to intervene. Though no exponent of that form of heroic surgery which is manifested by dramatic scenes in the operating theatre, Matas has always been prepared to fight with death not only during an operation but for long hours afterwards at the bedside, and even in desperate cases his skill has sometimes been victorious. The final contribution to the volume is a note by Dr. Evarts A. Graham on the reaction of bronchial fistulæ to acute respiratory infections.

The book is admirably printed on beautiful paper. It has 102 illustrations, five in colour, and a portrait of Dr. Matas. It is a work worthy of the man in whose honour it is written.

The Causation of Chronic Gastro-duodenal Ulcers.

By J. JACQUES SPIRA, M.R.C.S.Eng., L.R.C.P.Lond. London: Humphrey Milford, Oxford University Press. 1931. Pp. 78. 7*s.* 6*d.*

IN the preface to this book Dr. Spira apologises for recapitulating a number of known facts which have forced him to include a great number of references. We feel that if any apology is necessary for the publication of so well written a work, it should be for launching upon a harassed world a theory, exposed by the author with ingenuity and eloquence, but without, as far as we can ascertain, a single attempt on his part to support it by experimental work. Dr. Spira is, in fact, one of those who would impose upon others the ungrateful task of testing his own ingenious ideas. He believes that the regurgitation of bile into the stomach and excess of fat in the diet are the chief factors responsible for the production of chronic gastric ulcer. He has read a lot, and his reading enables him to select quotations and experiments from over a hundred authorities in support of his personal theory. Without for a moment purposing to do so, we suggest that it would be equally possible to select from the same authorities quotations and experiments which are against his theory. He says, "the final test of the value of this theory must entirely depend upon the results obtained from its clinical application." How many thousands of inert substances have been offered to the medical profession and their patients during the last ten years with convincing recommendations somewhat similarly worded? Why, if Dr. Spira's theory is correct, are there admittedly such good clinical results obtained from forms of treatment which not only ignore his theory, but are often framed in such a manner as to be doomed to failure if his theory represented the whole or even the greater part of the truth?

We feel that no good can come of a more detailed review of this book, which we have examined with great care. It may fairly be described as a well-written thesis quite unworthy of general acceptance until such time as its author is prepared to abandon the collection of literature, and to perform a few crucial experiments by which alone the value of his theory can be tested.

Journal of Pathology and Bacteriology.

THE January number (Vol. XXXV., No. 1) contains the following papers: A case of reticulum cell carcinoma of thymus, by S. McDonald, Junr. (Newcastle). A full description of an example of this rare condition in a man of 59.—Mitosis in the hepatic metastases of malignant tumours, by R. A. Willis (Melbourne). By actual enumeration of the proportion of cells in mitosis it is shown that hepatic metastases proliferate much more quickly than the primary tumour, and it is suggested that the liver provides a particularly favourable environment for growth.—Sacculated intracerebral aneurysm of the middle cerebral artery, by W. H. Chase (Montreal). In a woman of 30. The histology shows that the aneurysm developed as the result of a congenital defect of the media at a point of branching.—Polypi coli, by W. Susman (Manchester). Polyps of the colon are found in about 5 per cent. of autopsies if they are carefully looked for; of the author's 65 examples, malignancy had developed in four, and in 15 there was carcinoma coli as well.—The action of anti-vaccinial serum on the vaccinia virus, by R. W. Fairbrother (Manchester). The serum soon neutralises the virus if intradermal testing is used, but such mixtures will fatally infect if given into the brain.—The results of intrathecal inoculation of the virus of poliomyelitis in monkeys, by E. W. Hurst (London). The virus does not spread as dyes do, and there is no reason to suppose that the cerebro-spinal fluid is important in its dissemination.—A comparison of the changes in the blood-sugar and blood phosphorus in rabbits following the injection of suspensions of different dead bacteria, by M. E. Delafield (London).—Plasmacytoma of the nasopharynx, by J. W. S. Blacklock and C. Macartney (Glasgow). In a man of 64, and possibly granulomatous rather than neoplastic.—An alcohol-soluble antigen (substance Q) in salmonella agglutination, by P. Bruce White (London). For agglutinin experts.—The dilution ratio of diphtheria antitoxin as a measure of avidity, by A. T. Glenny and Mollie Barr (London) (see p. 252).—The relative incidence of human and bovine tubercle bacilli in tuberculous meningitis in England, by A. S. Griffith (Cambridge). Nineteen of 63 cultures were of bovine type, whence it may be surmised that about 700 persons die each year in England and Wales from tuberculous meningitis of bovine origin.—Capillary hæmangioma of spinal cord associated with syringomyelia, by Dorothy S. Russell (London).—The relation of the liver to the disposal of hæmoglobin, by R. Muir and J. S. Young (Glasgow). Hæmoglobin free in the circulation is not taken up by the liver.—The development of agglutinins for elementary bodies in the course of experimental vaccinia and fowl-pox, by J. C. G. Ledingham (London). After inoculation with vaccinia rabbits sera develop agglutinins for the minute bodies found in the lesions which may well be the virus itself. The antibody curve runs a course differing in no essential particular from that characteristic of ordinary bacterial infections.—Dissociation in vivo of diphtheria toxin-antitoxin mixtures, by A. T. Glenny and Mollie Barr (London) (see p. 252).—Preservation of cultures under liquid paraffin, by H. J. Parish (London). Useful for meningococci and other delicate organisms.—Endometriosis carcinomatosa, by C. Oldfield and M. J. Stewart (Leeds). Malignant endometrial tissue extending through the whole substance of the uterine wall.—Liposarcoma of the broad ligament, by C. Oldfield and M. J. Stewart (Leeds). With a fibrosarcoma of the cervix.—Neurofibromatous epulis, by E. M. Hickman (Leeds). In a boy of 8 with no other signs of von Recklinghausen's disease.

Obituary notices of R. M. Buchanan (portrait), A. S. Warthin (portrait), W. E. Dixon, J. S. C. Douglas (portrait).

NOVARSAN 0·75 Gram
NEOARSPHENAMINE
(PUSON)
Manufactured by SYNTHETIC DRUG CO. LIMITED Toronto, Canada
Imported by ALLEN & HANBURYS LTD., LONDON
Under Import Licence No. 6
NOVARSAN
ARSENOBENZ

An Empire Product

'NOVARSAN' BRAND

NEOARSPHENAMINE

(formerly called novarsenobenzol)

combines high spirochæticidal and therapeutic activity with low toxicity. "Novarsan" is manufactured in Canada and is sanctioned by the Ministry of Health for use in clinics.

Each batch is passed by the Medical Research Council.

The outfits are supplied for either Intramuscular or Intravenous use.

Further particulars will be sent on application.

Allen & Hanburys Ltd., London, E.2

Telephone: 3201 Bishopsgate (10 lines). Telegrams: "Greenburys Beth London."

After Influenza the Ideal Tonic is

Rx Bynin Amara

Sig ʒi ex aq t.d.s.p.c.

COMPOSITION:

Quinine Phosphate	1½ gr.
Iron Phosphate	2 gr.
Nux Vomica Alkaloids equal to Strychnine	1/16th gr.
'Bynin' Liquid Malt	1 oz.

Further particulars and clinical trial sample will be sent on request.

NDON: SATURDAY, JANUARY 30, 1932.

BRONCHOSCOPY.

UCH water has flowed under the bridges since OLINI, in 1875, first made a direct examination he trachea and larger bronchi by means of a e passed through a tracheotomy wound. For years or more after VOLTOLINI's experiments ious isolated attempts were made to examine trachea and bronchi directly, the chief being t of KIRSTEIN; but the really serious study of nchoscopy began with KILLIAN, whose work 97) was continued by BRÜNINGS, and these two n may be said to have laid the foundation of r knowledge on the subject. KILLIAN and ÜNINGS, using proximal illumination of their strument, were followed by EINHORN, whose genious idea of distal illumination led up to the illiant technique of CHEVALIER JACKSON. The ses which he described a year ago in moving ctures to the Medical Society of London[1] were a velation to many who were present, and there is tle doubt that his inspiration has had much to with the increasing interest in bronchoscopy in is country. During the period of ten years ding 1928 bronchoscopic examinations to the umber of 7373 were performed in his clinic at hiladelphia, and some estimate of this work can e made from the fact that one of his assistants, r. C. J. BUCHER, recently published[2] the bacteriogical findings in 118 cases of pulmonary abscess reated by means of the Jackson bronchoscope. f recent years F. HASLINGER has introduced a ew instrument, extensively used in his clinic at ienna, retaining the proximal illumination of RÜNINGS. Numerous other instruments are in se, most of them modifications of JACKSON's.

In our present number we give an account of the se of bronchoscopy for diagnostic purposes by Dr. A. J. SCOTT PINCHIN and Dr. H. V. MORLOCK who, having used the Jackson and Haslinger nstruments in their earlier work, have now lesigned a modification of the former with several new features. Improved forward illumination with a view of the orifices of lateral bronchi is attained by an alteration in lens position, whilst a magnified image is produced by means of a telescope—which incidentally protects the operator from being soiled with expectoration if the patient coughs. An operating telescope provides facilities for the use of forceps and drainage-tube under direct guidance, and a rotary cylinder exhaust pump provides more efficient drainage than has hitherto been possible with previous instruments. In their clinic at Victoria Park they have examined some 450 cases during the last 12 months. On the diagnostic side, with which the present paper only deals, a number of points are raised. In the first place it is made clear that bronchoscopic examination can be used by any physician who is prepared to take pains to acquire the technique. JACKSON himself once carried a bronchoscopic outfit with him on a fishing holiday and spent his time extracting fish-hooks embedded in rubber tubes whilst his colleagues angled. Bronchoscopy is no field for amateur effort: the responsibilities are too serious. But, once the technique is acquired, it is likely to become, like collapse therapy, an important part of the day's work. The cases recorded this week are instructive in their possibilities. In the pulmonary neoplasms, with partial or complete blockage of the bronchus and collapse of lung or suppuration beyond the obstruction, the diagnosis was often made on bronchoscopic examination of the distal portion of the bronchus after other methods of investigation had failed. For the moment the cases of chronic pulmonary suppuration, especially lung abscess, are of prime importance, for here cure may follow accurate diagnosis. Thus a case which had defied diagnosis for four months proved, on bronchoscopic examination, to have an abscess cavity, with an inflamed external division of the right lower-lobe bronchus which prevented natural drainage. Bronchoscopic drainage resulted in cure. In another instance an unsuspected hydatid of lung was diagnosed. Two other cases may be quoted from the record as instructive: an unexplained hæmoptysis of three years' duration was found on bronchoscopic examination to be due to the presence of a vascular septum opposite the right middle-lobe bronchus, and cured by cauterisation; in a sputumless case with doubtful basal signs the bronchial swab revealed the presence of tubercle bacilli.

The writers point out that bronchoscopic examination does not disturb the patient more than the removal of a tooth under local anæsthesia: in more than one-third of the 450 cases of bronchoscopy—all of which were done under local anæsthesia—the patient was able to go home two or three hours later. The fact that patients return regularly to the clinic week by week for the treatment of pulmonary suppuration by this means is an indication of their readiness to submit to repeated bronchoscopy. The establishment of a clinic for this purpose in a chest hospital is evidently a step in the right direction, for the steady down-hill career of many of these cases has hitherto presented a baffling problem for the physician. It may well be that in due course the bronchoscope, which has hitherto been regarded as part of a surgeon's equipment, will become to the physician as valuable as the pneumothorax outfit and the thoracoscope.

Reminders and Suggestions

For the
Treatment of
INFLUENZA, PNEUMONIA,
COUGHS, COLDS, BRONCHITIS, etc.

KINECTINE

An organic arsenical salt of Quinine indicated in Influenza, Acute Coryza, etc.

Tubes of 10 Tablets: Dose—One three times a day.

CRYOGENINE

(Lumière)

A particularly safe and reliable analgesic and antipyretic in all febrile conditions. Bronchitis, Pneumonia, Influenza, Pleurisy

Powder and Tablets: Dose—From 0·50 to 2·50 gm. daily as required.

ORARGOL

An electrically prepared Gold-Silver Colloid for general antisepsis and effective colloidotherapy.

Ampoules of 5 c.c. and 10 c.c.

By intravenous or intramuscular injection Orargol is capable of aborting serious cases of Influenza and Pneumonia, and exerts an antitoxin-like effect in acute infectious conditions.

Also supplied in special O.R.L. Outfit for Nasal Irrigation in the treatment of Rhinitis, Tonsillitis and Naso-pharyngeal inflammations.

Extremely valuable as a prophylactic against Colds and Influenza.

SYRUP CREOSAL

(Dubois)

A combination of Guaiacol, Calcium and Phosphoric Acid pleasantly flavoured with Syrup of Orange Flower & Cherry Laurel

An excellent specific for Coughs—whatever their origin—Bronchitis, Laryngitis, and all Catarrhal Conditions.

SYRUP PERTUSSIS

(Gabail)

A combination of deodorised Valerianate, expectorants and sedatives presented in a palatable form with Syr. of Raspberry.

An effective medicament for the Paroxysms of Whooping Cough.

LITERATURE AND SAMPLES ON REQUEST FROM

The Anglo-French Drug Co., Ltd.,
238a, Gray's Inn Road, LONDON, W.C.1.

ibsidiary problems of vision affecting infants school-children. The Physiology of Vision mittee of the Medical Research Council have consulted with the object of arranging for an inquiry, and it seems likely that the project materialise.

JRTHER PROGRESS IN THE ISOLATION OF THE VITAMINS.

FTER a long preliminary period in which ation of vitamins seemed a very remote possi- y, we have suddenly arrived at a time when orts of isolations jostle one another for room in press. Within the last few weeks fresh claims e been made concerning vitamins A, B_1, C, and The work of O. and A. RYGH[1] on the anti- rbutic vitamin C was briefly mentioned in our ding article of Dec. 12th, 1931, but examination the paper by them which has since become ilable cannot be said to inspire confidence. They that narcotin, irradiated with ultra-violet light, l one of its derivatives, prevented the develop- nt of symptoms of scurvy in guinea-pigs on a rbutic diet; but the number of animals used is ry small and they were all in bad health or tually died, even though symptoms of scurvy re not recognised. Further, they found that rvy was not prevented by doses of material ghtly higher than those which did prevent it—a ry ususual phenomenon. As regards vitamin B_1, NDAUS and his co-workers,[2] previously asso- ated with the isolation of vitamin D, claim to have epared a crystalline antineuritic vitamin from east. Rice polishings is the material which has therto most generally been used for the prepara- on of concentrates but in this case the same ethod, the well-known one of JANSEN and ONATH, has been applied to yeast. A crystalline icrolonate, chlor-aurate, and hydrochloride were repared and the hydrochloride, when injected into igeons suffering with polyneuritis, was effective n a minimum dose somewhat smaller than that f any previously prepared concentrate. A formula s assigned to the substance, which differs from JANSEN and DONATH's by including sulphur in the molecule. At the Royal Society last week, a description was given of the further purification, by R. B. BOURDILLON and his team, of their crystalline preparation of vitamin D. The product previously obtained by vacuum distillation of the products of the ultra-violet irradiation of ergo- sterol was further purified by esterification, by which process the antirachitic activity was doubled. The substance thus obtained is believed to be the same as the vitamin D_2 of O. LINSERT and A. WINDAUS. It would appear also that the vitamin D_1 of WINDAUS is a compound of vitamin D_2 with an inactive substance, referred to as sterol *x*. For vitamin A an isolation is announced by P. KARRER[3] and his co-workers and J. C. DRUMMOND, I. M. HEILBRON, and R. A. MORTON. The substance obtained by KARRER is not from the classical source, the cod's liver, but from the liver of other fishes (*Scombcresox saurus*, a species of mackerel, and *Hippoglossus hippoglossus*, the halibut); the liver oil of both of these is vastly richer in vitamin A than that of the cod. The final separation was effected by fractional adsorption on fibrous alumina and subsequent elution. The product was an alcohol and could be esterified; when recovered from the ester it had the same composition and gave the same value with the antimony tri-chloride test as before. The formula given is either $C_{20}H_{30}O$ or $C_{22}H_{32}O$. A specimen obtained by distillation gave the same values. A molecular weight of 300–320 is suggested and two structural formulæ are very tentatively put forward; in both of these there is structural resemblance to carotene. It is admitted that this substance may be, though improbably, a mixture; sufficient time has not yet elapsed for the results of the all-important biological test to be known. DRUMMOND and his co-workers announced the result of their isolation of vitamin A to a meeting of the Society of Chemical Industry on Jan. 4th. Their preparation was also made from halibut-liver oil, by a process of fractional distillation, and the formula ascribed is the same as one of those obtained by KARRER. Doubtless, in both these cases, the work of isolation has been greatly facilitated by the use of a source of the vitamin so much richer in it than cod-liver oil, on which previous attempts were made.

◆

VITAL STATISTICS FOR 1931.

THE Registrar-General has issued a provisional statement of the figures for birth-rate, death-rate, and infant mortality during the year 1931.

—	Birth-rate.	Death-rate.	Infant mortality-rate.
England and Wales..	15·8	12·3	66
107 county boroughs and great towns including London ..	16·1	12·3	70
159 smaller towns ..	15·6	11·3	62
London	15·0	12·6	67

The smaller towns are those with a population in 1921 of 20,000–50,000. The birth- and death-rates for England and Wales relate to the total population and are calculated on the estimated mid-1931 population. The remaining rates are calculated on provisional resident population based on the 1931 Census figures and relate to the total population for births but to the civil population only for deaths. Birth-rate (live-births) and death-rate (crude) are per 1000 population, infant mortality-rate per 1000 live-births.

The Registrar-General remarks that the birth-rate is the lowest on record, being 0·5 per 1000 below the previous lowest, recorded in 1929 and 1930. The death-rate is 0·9 above that for 1930. The infant mortality-rate is 6 per 1000 above that for 1930, but only in 1928 and 1930 has this rate been lower. These provisional figures, which are not likely to require substantial modification, have been issued for the information of medical officers of health and others.

REFRACTION OF THE EYES IN CHILDREN.

THE normal refraction of children at various ages is not easy to ascertain. It is known that the eyes of any child at birth are practically always hypermetropic with or without astigmatism. At the age of 15, however, though the condition of astigmatism, if any, will be little changed, the eyes may be either hypermetropic, emmetropic, or myopic. In a report issued by the Board of Education on an inquiry into problems connected with defective vision in school-children,[1] it is suggested that a further inquiry should be undertaken to establish a "basic scale" to determine the normal—i.e., average refraction in boys and girls of each age-group from 1 to 15. The report, which has been compiled by a committee under the chairmanship of Sir GEORGE NEWMAN, does not go very far in establishing such a basic scale, but it helps to define our knowledge of the general trend of the refractive changes in childhood, and it suggests certain improvements in the methods of dealing with the problems of vision in the schools for the consideration of education authorities. 2625 unselected children between the ages of 1 and 15 were studied, their refraction being determined by 22 skilled observers according to a uniform scheme laid down by the committee. The main conclusions reached were that simple hypermetropia is by far the commonest condition of refraction met with in children of school age and under, but that the incidence decreases as the age increases, the highest incidence being 87·4 per cent. in the boys of 1–2 age-group and the lowest 53·1 per cent. in the girls of 13–15 age-group. Whether the actual peak in the incidence of hypermetropia comes immediately after birth or between the ages of 1 and 2 appears to be uncertain. Emmetropia is comparatively rare in children under 5, being observed in only 2–3 per cent. of children at the age of admission to school. Later, the incidence increases but does not exceed 10 per cent. in children about to leave school. Myopia is decidedly rare in children under five, only five cases being found in 1166 examinations. With the higher age-groups the incidence increases. Cases followed up during a period of years provide examples of children gradually becoming more myopic as their age increases or actually changing from low hypermetropia to myopia. Astigmatism in children is generally hypermetropic, the incidence of this form varying between 10 to 20 per cent. in the different age-groups, but without, apparently, any definite relation to the age. Some individual children who were re-examined at intervals showed a gradual all-round reduction of hypermetropia, others a reduction affecting one axis, usually the one of higher hypermetropic value. Cases of myopia and mixed astigmatism were too few to base any general conclusions on, but examination of individual children revealed the expected process of change towards an increase of myopia in one or both meridia.

The results of the inquiry, as summarised in the report, "indicate that normally the eyes of children are in a dynamic condition; that at birth the normal condition is one of hypermetropia which is converted as time goes on to one of emmetropia; and that over-action in this otherwise normal process produces a condition of myopia." A practical point arising out of the establishment of this general law is concerned with the prophylaxis of myopia. Emmetropia in the young child is exceptional and may indicate a liability to myopia as the child grows older. It may be desirable that such children should be subjected to more frequent periodical examinations than others, in order that special consideration should be paid to them in the school routine before it is too late. Another practical point concerns hypermetropes. In the routine examination of the State schools the only test at present employed to select those needing special examination is ability to read accurately the distant test-type. In this test the child with a moderate degree of hypermetropia is at no disadvantage compared with the emmetrope, since he has ample power of accommodation, and the test fails to reveal how much of it he is employing. When he is using his eyes for close work the long-continued tax on his accommodative muscles may be undesirable, and may cause a form of what is generally known as "eye-strain." In conditions of enfeebled health from any cause this is only too likely to happen. The report suggests that the present system of examination is defective in this respect and might be improved. It would be comparatively easy to select those children with any considerable manifest hypermetropia for special examination under a mydriatic, though to lay down a general rule that a certain amount of hypermetropia at a certain age called for the prescription of glasses irrespective of the visual acuity would obviously be unwise. It would be well, however, that such cases should be watched so that, if general lassitude or other symptoms should occur, the possibility that glasses are needed should not be forgotten. The treatment of these children should be [illegible] individual rather than on general lines.

A reorganisation of the present system of vision testing in schools would involve a slight increase in the work and therefore in expenditure, but it would almost certainly result in an ultimate economy from the national point of view. Incipient myopes and hypermetropes would certainly be benefited by a change of policy. The committee believe, however, that a more accurate determination of the "basic scale" would supply [illegible] information of much value. They recognise that their present report needs supplementing, and that owing to the compromises necessary in [illegible]ing general conclusions from a large number of individual figures some possibilities of fallacy may have crept in. They therefore suggest that an individual whole-time worker—not a committee—be appointed to make a further investigation. The investigation, which would probably take about two years, should be so planned as to cover not only the "basic scale" but a number ure of that which the boys acquired in their es; a minimum measure, since only a single nination was made, apparently by smear, and since worms may well have been lost in the meantime. ugh the figures are too few to be of statistical e in measuring hookworm incidence in the endemic of the United States, they yet fall fairly close to rs which are. These were supplied to Stiles by e medical officers of health, and they show ; microscopical examination detected hook-m eggs in the fæces of 28·1 per cent. of 121,388 ons investigated in 1929 compared with 33 per t. of 1,087,665 examined between 1910 and 1914. se percentages are not exactly comparable since y were obtained by various techniques, and such er greatly in exactness; yet they serve to show difficult problem which confronts those who ect hookworm campaigns, seeing that in a country the forefront of our present civilisation, steady rk against the hookworm has made such little dent advance in 20 years.

---

[1] H.M. Stationery Office. 1931. 9*d*.

But the objection will certainly be made that these ures take no account of any lessened intensity of ection, of that smaller number of worms per head the infected which the work of 20 years has sumably effected. The view is, indeed, widely ld that hookworm infection can be graded from ry light to very heavy according to the worm load ried, and that this grading has clinical significance. this classification a "moderate" infection is fined as one with between 101 and 500 worms. lthough these supposed worm loads are only infer-ices from egg counts made by a particular tech-ique, it is assumed that they have exact, uncon-itional and individual application. On this point ght has been thrown by L. Schapiro and E. G. auck.[2] They carried out 400 routine post-mortem xamination at the Hospital San Juan de Dios, Costa ica. All details necessary for the purpose of their aper were contained in reports on 78 whites and ne negro. Twenty-four of these 79 persons died directly from hookworm disease, showing the well-ecognised anæmia, general tissue œdema, and fatty degeneration of heart, liver, and kidneys; in them he number of hookworms was determined by careful earch of the whole length of the intestines; and the verage hookworm load was 257, in spite of the fact hat in one body 1262 necators were recovered, the number of ankylostomes not being stated. In the 55 persons dying from causes other than hookworm infection the average load was 26. While then the average load of those killed by these parasites corresponded at the time to death to the class of case which, on mathematical lines, is graded as "moderate," there must have been some of them who would have fallen into the "light" and "very light" mathematical grades, since the writers emphasise the fact, known for many years, that the clinical gravity of a case is not measured by the number of worms harboured at any moment, including that of death. Whether more worms have been harboured earlier in fatal cases is in the nature of things almost impossible to determine, since they are seen only in the last stages. At all events, in these cases the average lethal load was 257. There is an impression that a particular load of *Ancylostoma duodenale* is more harmful than an equal one of *Necator americanus*, and that the latter is essentially the worm which will be found in America. In Costa Rica necators and ankylostomes were as 53 to 47; the last five years have shown that a high or preponderant percentage of the latter has been present in Panama, Paraguay, and Tucuman. Wider and closer search may well extend the distribution of these supposed anomalies.

Schapiro and Nauck also made egg counts of the intestinal contents above and below a point in the transverse colon, and correlated these with the worm counts made from the same bodies. Since during life the egg counts for such correlations are made from fæces, it seems necessary to consider only those made from the lower colon, and perhaps merely to point out that in the first two items of a table furnished by the writers the eggs in this portion of gut were as 197,000 is to 3000, while the numbers of female worms were respectively 318 ankylostomes and 56 necators, and again 36 ankylostomes and 243 necators. Making the fullest allowance for all possible difference in laying power between the two species concerned, these figures show how erratic such correlation may well be. These latest workers add to the evidence countering the assumption that the estimation of worm loads by egg counts is a simple matter; nor does that evidence support the mathematical view that infected persons may confidently be graded into classes of clinical value. Hookworm infection is no more a mathematical problem than are the other ills of man. As Lord Dawson has put it, "Disease is not a standardised product, for, thank heaven, man preserves his individuality in sickness as well as in health; otherwise it would be an uncommonly dull world to live in."

HEREDITY AND SCHIZOPHRENIA.

THAT heredity plays an important part in the ætiology of schizophrenia has long been recognised. In a recent study of the subject,[1] Manfred Bleuler, the son of Eugen Bleuler, has examined the pedigrees of 100 schizophrenic patients at Bloomingdale Hospital, White Plains, New York. Briefly his findings were as follows: The 100 patients had 351 siblings among whom were 39 psychopaths and marked eccentrics, 9 schizophrenics, and 9 sufferers from other forms of mental disability or defect. Among the 200 parents of the 100 patients were 46 psychopaths and marked eccentrics, 4 schizophrenics, and 14 sufferers from miscellaneous disabilities of psychiatric significance. Among 1109 grandparents and collateral relatives, there were 122 psychopaths and eccentrics, 5 schizophrenics, and 23 sufferers from other mental disturbances. It will be obvious that the records of this last group must have been very incomplete. Dr. Bleuler tentatively discerns a group of six somewhat distinctive cases, in the causation of whose psychoses hereditary and familial factors appear to play no part. These six cases have certain common characteristics. They are obese dysplastics who, before the onset of the psychosis, were good-natured, sluggish, and of somewhat inferior intelligence. The illness began between puberty and the age of 26; its course was rapid and without remissions; and it terminated in a condition of advanced dementia in which the patient yet retained a capacity for affective rapport of the kind sometimes observable in idiots.

The author finds, too, that a familial incidence of abnormal traits is most marked in those patients whose schizophrenia exhibits manic-depressive features. In conducting this investigation, however, he has encountered a difficulty which, in the present state of our knowledge, is almost insuperable. Where is he to draw the line between normality and "marked eccentricity"? Of this last category, the

ANNOTATIONS

BIRMINGHAM HOSPITALS CENTRE.

A FORTNIGHT ago, by a majority of 42 out of 470 votes, the subscribers to the scheme for a great Hospitals Centre for Birmingham authorised the executive to proceed with the first part of the plan. This decision was reached at a meeting of the contributories over which the Lord Mayor of Birmingham presided, and at which full statements of all sides of the case were made. The proposed centre is the joint extension scheme of the General and the Queen's Hospitals and will be under the joint management of their boards, and is the result of a unanimous recommendation by a joint committee appointed by the Hospitals Council composed solely of members of the two hospitals. When the project for the establishment of a hospital centre with a medical school in proximity to, and working in connexion with, the University was first mooted it met with general acceptance, and in 14 months £620,000 (including the value of the site) was promised towards its realisation. Some interesting designs were obtained on open competition and the winning design was remarkable for its broadminded recognition of all the needs of a hospital community.[1] Of late, however, the general economic situation has aroused misgivings, and when it was decided to obtain tenders for erecting the first portion of the buildings an agitation arose which had for its object the abandonment of the scheme or, at least, its postponement to a more propitious season. It was urged that it would be impossible in present circumstances to erect and maintain a hospital with 500 beds and a medical school without seriously risking the whole voluntary hospital system of the city. In addition to the £702,000 which the work was estimated to cost, the matter of maintenance loomed up formidably. On the other hand the hospital, when completed, will have 100 pay beds, the need of which is generally admitted. In the 12 months ending with August last, the General Hospital turned away more than 2000 cases officially stated to be in need of "urgent in-patient treatment." Even so the hospital is so short of bed accommodation that day-rooms have had to be turned into wards, while, as the result of the persistent congestion, patients have had to be discharged before their time. Special departments are overcrowded, and there is no room for their expansion. One of the advantages claimed in favour of immediately starting upon the work is that economy will be consulted by the inclusion of certain of the service departments required for the complete scheme. Since the meeting referred to, however, the executive board have decided to postpone action until the beginning of next year. Meanwhile a joint appeal is being made by the General, the Queen's, and the Ear and Throat Hospital for £90,000. Of this sum £50,000 is asked for by the General Hospital, which last year treated more than 8000 in-patients and over 54,000 out-patients and casualties.

DIPHTHERIA IMMUNISATION.

THE deliberate immunisation of children against diphtheria is one of the most substantial advances made in recent years in sanitary bacteriology. There have been troubles and a few accidents, and our knowledge of the details of exactly what happens when toxin rather than toxoid is used is still not wholly complete. The procedure has, however, been abundantly proved to be sound and useful; that there is still room for improvement is shown in two papers published in the last number of the *Journal of Pathology and Bacteriology* (1932, xxxv., 91 and 1[illegible] by Mr. A. T. Glenny, D.Sc., and Miss Mollie Barr of the Wellcome Foundation at Beckenham. All preparations of antitoxin do not combine equally firmly with toxin, and with some of them a mixture which is neutral to a test animal in a volume of 1 c.cm. may become poisonous if it is made up with saline to 100 c.cm. That is, the toxin-antitoxin compound dissociates when it is diluted. They now show in a series of exceptionally interesting experiments that the same kind of thing may happen in the body. Thus in one experiment a series of rabbits were injected intravenously with varying quantities of the same toxin-antitoxin mixture. The animal which received 0·0005 c.cm. survived, seven rabbits which had doses from 0·001 to 0·1 c.cm. died between the fourth and eighth days, while five which received doses ranging from 1 to 10 c.cm. all survived the tenth day. The first animal lived because the amount of toxin it received was not enough to kill it, the last because the dose was so large that when it was diluted in the body fluids the degree of dissociation was not sufficient to set free a fatal amount of toxin; the intermediate animals died because they had more than enough toxin and the dilution in the body was enough to set it free. Was ever the treachery of a simple experiment so well illustrated? And Dr. Glenny substantiates his explanation by a brilliant corollary. Give a rabbit 10 c.cm. of the mixture; it will come to no harm. Two hours later draw off some of its blood and inject 1 c.cm. of its serum into other rabbits which will die unless they are protected with an adequate dose of antitoxin. It seems evident from these experiments that a toxin-antitoxin mixture which proved harmless when tested on guinea-pigs might be poisonous in a child, and it is not easy to devise any simple method of testing which would expose dangerous mixtures with certainty. For practical purposes it is fortunately unnecessary to solve these particular difficulties, since all possible source of danger can be avoided by using, instead of toxin, the modification of toxin prepared by treating it with formalin. This toxoid is not and cannot become poisonous, and it is as efficacious as toxin as an immunising agent for human use. It is clear that toxin-antitoxin mixtures should be given up.

THE MINIMAL LETHAL HOOKWORM LOAD.

Two winters ago the fæces of 73 inmates of the National Training School for Boys, Washington, were microscopically examined at the National Institute of Health and the results are now reported by C. E. Baker.[1] Sixty-seven of them came from the hookworm area of the United States, and they showed a detected hookworm infection rate of 34 per cent. C. W. Stiles[2] has already reported that none of these boys was seriously ill; some were clinical suspects, while regarding several he would have been prepared to make a diagnosis of hookworm disease on their histories, and on physical examination quite independently of the microscope. The school being urban in site and sanitation, it is unreasonable to suggest that this infection was acquired in it; it becomes then a of X rays to widespread metastases, has led school of thought to rely on small doses. The site school adopts the policy of maximal dosage hich the object is to kill each malignant cell. ig care to protect, as far as possible, the healthy e from irradiation. This direct method puts a re strain upon the patient and courage is often ed to apply a dose deemed large enough to icate the disease. The aim is to subject a given me of malignant tissue to uniform irradiation, it is claimed that an increase in the penetration of rays used leads to improved results—which is to expected from purely physical considerations if ormity of irradiation is the desideratum. To in still greater uniformity of irradiation radium ften implanted in the deeper layers of the growth n beneficial results. How the large doses used in method should be administered is a question ch is engaging many radiologists at the present e. Should the dose be given as a whole or subided? The general opinion of those advocating vy doses of X rays appears to be that split doses more beneficial than single doses. There is, vever, no general consensus about the magnitude the fractional doses to be applied to particular es of growth or the duration of time between plications.

TREATMENT OF SUBACUTE COMBINED DEGENERATION OF THE CORD.

Liver treatment has never given the same conmt improvement in the nervous symptoms of bacute combined degeneration of the cord as it has the associated anæmia. This fact has been explained two ways. It has been maintained, in the first ace, that since the lesion is, at least in its late age, an actual degeneration of nerve tissue, complete recovery could not be expected. This view has ceived some corroboration from the finding that ses with an acute history, in which probably actual estruction of tissue has not yet taken place, do uch better than the more chronic. Secondly, r. C. C. Ungley[1] has suggested that the nervous sion is due to the lack of some factor other than he effective principle in liver, and in our present ssue he describes clinical observations to support his hypothesis. He has previously shown that the æmatopoietic potency of brain is only one-third f that of liver. Now, from treating a series of patients with severe cord lesions first with liver and then with brain, he concludes that the effect of brain upon the nervous system is markedly greater than that of liver. What the possible factor in brain may be he does not indicate, but it is clearly not vitamin A, a lack of which E. Mellanby[2] thought might be responsible for the lesions, since brain contains little of this substance. The improvement noted in Dr. Ungley's cases is definite; but it must be remembered that all observers agree that it is necessary to persist in treatment in order to benefit the nervous symptoms, and in the present experiment brain succeeded liver. Further, brain had the advantage of being given while the patients were under constant supervision, thus ensuring adequate dosage.

In another paper, on p. 230, Dr. W. Sargant suggests that iron in massive dosage will produce what is almost a biblical cure of the nervous symptoms. Knowing that the effects of liver are far from satisfactory, and acting on the observation that the blood picture is rarely of a typical pernicious type, he treated four cases, having severe nervous symptoms, anæmia and achlorhydria, with large doses of Blaud's pill. Within a few weeks two patients who were unable to walk unaided could do so, and the others were much improved. The importance of these observations is unquestionable, since the apparently incurable were cured; but their exact interpretation is open to question. Few would agree with the statement in Osler and McCrae's textbook that in subacute combined degeneration the blood picture of secondary anæmia is more common than that of pernicious anæmia. In fact, such cases in which there is no apparent anæmia may yet show a typical Price-Jones curve. Unfortunately Dr. Sargant gives no exact information concerning the character of the red cells before treatment. In all his cases there was striking hæmatological as well as neurological improvement independent of the initial colour-index. Since iron does not affect the blood picture in pernicious anæmia, except in rare cases with a dual deficiency, while the typical iron deficiency anæmia as described by L. J. Witts does not show nervous symptoms, it seems possible that his four cases fall into a group which has not been hitherto recognised. It is clear that we have still much to learn of the relationship of changes in the hæmatopoietic and nervous systems, and that this knowledge can only come from accurate clinical experiment.

SCOLIOPATHEXIS.

Under this title Dr. Egerton L. Pope,[3] professor of medicine in the University of Alberta, describes a group of conditions whose importance is undeniable. Scoliopathexis indicates a perverted state of mind in relation to disease and has as sub-groups pathomimesis, identical with malingering, and pathopleiosis, which includes the clinical types of valetudinarians, neurotics, lead-swingers, and cases of "nerves." The increase of social care for the sick, and of the legal responsibility of employers and others for accidents, is associated with a great increase in the number of such cases, and Prof. Pope appeals to his colleagues to recognise their responsibilities in lifting their patients out of their disabilities at the earliest possible date and before they have lapsed into the mire of scoliopathexis. This appeal he strengthens by warnings as to the pitfalls awaiting the clinician who fails to recognise the initial stage when compensation looms in the distance, and he notes that in pathopleiosis the outstanding motives are the acquisition of money in the form of damages, compensation, or sickness insurance, the escape from legal entanglements likely to result in financial loss or punishment, the desire for sympathy, the escape from distasteful social, domestic, sexual, and occupational relationships.

This vigorous polemic is rich in clinical information and a useful corrective to the pseudo-pathological conceptions underlying such terms as traumatic neurasthenia. Yet it contains elements of danger, and the appearance of "nerves" in the group of pathopleiosis is perhaps correlated with the absence from the bibliography of any reference to recent work on psychopathology. It is novel to read that "in the circulatory system, fainting fits, palpitation, and cardiac pain that is not cardiological, are put forward as distressing features," and to find classified as pathomimesis these well-known symptoms of an anxiety state. This is a author makes this highly significant avowal: "if we had made the concept more embracing, we could easily have included the great majority of the 294 siblings of the patients." Some of the quoted cases of psychopaths and marked eccentrics are hardly convincing. Here are two, of which the first is an example somewhat disturbing for medical readers.

[2] Mellanby, E.: Brain, 1931, liv., 247; see THE LANCET, 1931, ii., 917.

[3] Canad. Med. Assoc. Jour., January, 1932, p. 40.

> "26·66. Male, 41 years old, living in a foreign country. Known as an 'anxious physician' who is constantly in a state of solicitude about his patients."
>
> "30·74. Male, died at 32. Alert and optimistic, a splendid soldier. A heavy drinker who had indulged in alcohol for many years."

This is surely to cast the net widely. By slightly altering, in one direction or another, the line of demarcation between the normal and the "psychopath and marked eccentric," the percentages of the latter could be halved or doubled according to inclination. Too easily may the results of such an investigation depend on subjective factors in the author. They may depend, for instance, on the feelings he entertains towards his teachers and professional elders. If he honours and reveres these in a becoming spirit (as Dr. Bleuler does Prof. Ernst Rudin) he will be disposed to adopt criteria which will yield such data as will confirm their findings. If, on the other hand, he dislikes them, his drawing of the line will be such as to lead to wholly different results. Or the drawing of the line may be influenced by a desire, conscious or otherwise, to prove or disprove the hereditary nature of mental disorder.

In estimating the significance of genetic factors in mental diseases, the consideration of eccentricities and abnormalities in the ancestors and collateral relatives always plays a prominent part. Though the task is an exceedingly difficult one, it is desirable that an attempt be made by a competent psychiatrist or group of psychiatrists to lay down some sort of distinction between the normal and the abnormal. The line would necessarily be arbitrary, but this would not matter as long as it was definite. Its precise position should be such as to create the simplest possible criteria for the assignment of doubtful cases to one category or the other.

PEPTIC ULCER AND PULMONARY TUBERCULOSIS.

ALTHOUGH an association in the incidence of peptic ulcer and pulmonary tuberculosis has been postulated from time to time for at least three-quarters of a century, its existence has *at least as often* been both doubted and denied. Mills Sturtevant and L. L. Shapiro[1] conclude that it is the pathologists who have noted an association, while the clinicians for the most part have been sceptical of any connexion between the two disorders. They report an analysis of 7700 necropsies, made at the Bellevue Hospital, New York, among which there were 891 instances of active pulmonary tuberculosis, an incidence of, roughly, 12 per cent. Among the 120 cases with gastric ulcers and scars there were 43 in which the patient had suffered from active pulmonary tuberculosis at the time of death, an incidence of 36 per cent., or three times as high an incidence as amongst those without gastric ulcers. This difference, as it stands, is statistically significant. When the authors reject the cases of healed ulcer as possibly misleading, in that these ulcers may have existed and healed before the onset of the tuberculosis, the significant difference is not materially altered. Looking at the figures from another aspect, they find the incidence of ulcer of the stomach in all necropsies is 1·12 per cent. (86 in 7700), while the incidence of ulcer of the stomach in necropsies showing phthisis is 3·14 per cent. (28 in 891). The difference, 2·02 per cent., is three and a half times its probable error, and therefore significant by the ordinary statistical criterion. An association also is found in other groups of pulmonary and pleural diseases. Searching for a common factor the authors suggest cough: "It is known that vomiting is a cause of gastric erosions. Cough is similar physiologically, is accompanied by marked alterations in intra-abdominal pressure, and may be accompanied by vomiting, if severe and prolonged." The figures are certainly suggestive, but their meaning is by no means easy to grasp. A hospital population is a "select" population; those who die are a "selected" group *of those in hospital;* those who are submitted to necropsy are still further selected. To interpret the statistics of the post-mortem room is notoriously difficult; to argue from them to the living is dangerous. Possibly the only sound way to solve a problem of this kind is to record the relevant lesions found in a long series of cases in which death was due to accidental causes.

DOSAGE OF X RAYS IN MALIGNANT DISEASE.

SPEAKING at a discussion held by the Section of Radiology of the Royal Society of Medicine on Jan. 15th Mr. W. Mayneord said that, of the various effects of X rays, the *ionisation* they produce in air seems most capable of exact measurement. Accordingly all measurements of X ray doses should be in terms of the international r unit, and this with advantage might also be extended to radium therapy. The choice of this criterion is the more acceptable, he said, because over a fairly wide range of wave-lengths the absorption of X rays in air runs parallel to their absorption in tissue. Hence it is reasonable to suppose that the measurement of X ray doses in international r units affords a means of estimating their biological effects. From the practical standpoint the frequent measurement of the output of *X ray tubes is essential for accurate* dosage. When it is realised that the output of the tubes may vary considerably from day to day, the importance of such tests need not be stressed. In radium therapy, too, precise dosage depends on a knowledge of the amount and distribution of radium *in* each tube employed.

From the medical standpoint, on which Dr. Hernaman-Johnson and Dr. Finzi were the principal speakers, the discussion served to show that very many factors must be taken into account in the treatment of malignant disease. Apart from the determination of the doses of X rays which will be lethal to particular tumours—which is seldom an easy matter—there is the difficulty of deciding how best to cope with metastases, present or future. Because of this disturbing factor there appears to be a sharp difference of opinion about the best method of treatment. On the one hand the gratifying results often obtained by early workers using X ray apparatus of low output have led some to conclude that it is *possible to treat malignant disease* with some success without having recourse to doses of radiation strong enough to kill the primary growth. The measure of success sometimes attending the use of small doses is partly responsible for the view that the action of X rays is an indirect one, stimulating the patient's resistance to the disease. This idea, coupled with the belief that it is almost impossible to *administer* lethal

---

[1] Arch. Int. Med., December, 1931.

, of X rays to widespread metastases, has led school of thought to rely on small doses. The site school adopts the policy of maximal dosage hich the object is to kill each malignant cell. g care to protect, as far as possible, the healthy e from irradiation. This direct method puts a re strain upon the patient and courage is often ed to apply a dose deemed large enough to icate the disease. The aim is to subject a given me of malignant tissue to uniform irradiation, it is claimed that an increase in the penetration of rays used leads to improved results—which is to expected from purely physical considerations if ormity of irradiation is the desideratum. To in still greater uniformity of irradiation radium ften implanted in the deeper layers of the growth beneficial results. How the large doses used in method should be administered is a question ch is engaging many radiologists at the present e. Should the dose be given as a whole or subided? The general opinion of those advocating y doses of X rays appears to be that split doses more beneficial than single doses. There is, ever, no general consensus about the magnitude the fractional doses to be applied to particular es of growth or the duration of time between plications.

TREATMENT OF SUBACUTE COMBINED DEGENERATION OF THE CORD.

LIVER treatment has never given the same connt improvement in the nervous symptoms of bacute combined degeneration of the cord as it has the associated anæmia. This fact has been explained two ways. It has been maintained, in the first ace, that since the lesion is, at least in its late age, an actual degeneration of nerve tissue, comete recovery could not be expected. This view has ceived some corroboration from the finding that ses with an acute history, in which probably actual struction of tissue has not yet taken place, do uch better than the more chronic. Secondly, r. C. C. Ungley[1] has suggested that the nervous sion is due to the lack of some factor other than he effective principle in liver, and in our present sue he describes clinical observations to support his hypothesis. He has previously shown that the æmatopoietic potency of brain is only one-third f that of liver. Now, from treating a series of patients with severe cord lesions first with liver and then with brain, he concludes that the effect of brain upon the nervous system is markedly greater than that of liver. What the possible factor in brain may be he does not indicate, but it is clearly not vitamin A, a lack of which E. Mellanby[2] thought might be responsible for the lesions, since brain contains little of this substance. The improvement noted in Dr. Ungley's cases is definite; but it must be remembered that all observers agree that it is necessary to persist in treatment in order to benefit the nervous symptoms, and in the present experiment brain succeeded liver. Further, brain had the advantage of being given while the patients were under constant supervision, thus ensuring adequate dosage.

In another paper, on p. 230, Dr. W. Sargant suggests that iron in massive dosage will produce what is almost a biblical cure of the nervous symptoms. Knowing that *the effects of liver are far from satisfactory*, and acting on the observation that the blood picture is rarely of a typical pernicious type, he treated four cases, having severe nervous symptoms, anæmia and achlorhydria, with large doses of Blaud's pill. Within a few weeks two patients who were unable to walk unaided could do so, and the others were much improved. The importance of these observations is unquestionable, since the apparently incurable were cured; but their exact interpretation is open to question. Few would agree with the statement in Osler and McCrae's textbook that in subacute combined degeneration the blood picture of secondary anæmia is more common than that of pernicious anæmia. In fact, such cases in which there is no apparent anæmia may yet show a typical Price-Jones curve. Unfortunately Dr. Sargant gives no exact information concerning the character of the red cells before treatment. In all his cases there was striking hæmatological as well as neurological improvement independent of the initial colour-index. Since iron does not affect the blood picture in pernicious anæmia, except in rare cases with a dual deficiency, while the typical iron deficiency anæmia as described by L. J. Witts does not show nervous symptoms, it seems possible that his four cases fall into a group which has not been hitherto recognised. It is clear that we have still much to learn of the relationship of changes in the hæmatopoietic and nervous systems, and that this knowledge can only come from accurate clinical experiment.

SCOLIOPATHEXIS.

UNDER this title Dr. Egerton L. Pope,[3] professor of medicine in the University of Alberta, describes a group of conditions whose importance is undeniable. Scoliopathexis indicates a perverted state of mind in relation to disease and has as sub-groups pathomimesis, identical with malingering, and pathopleiosis, which includes the clinical types of valetudinarians, neurotics, lead-swingers, and cases of "nerves." The increase of social care for the sick, and of the legal responsibility of employers and others for accidents, is associated with a great increase in the number of such cases, and Prof. Pope appeals to his colleagues to recognise their responsibilities in lifting their patients out of their disabilities at the earliest possible date and before they have lapsed into the mire of scoliopathexis. This appeal he strengthens by warnings as to the pitfalls awaiting the clinician who fails to recognise the initial stage when compensation looms in the distance, and he notes that in pathopleiosis the outstanding motives are the acquisition of money in the form of damages, compensation, or sickness insurance, the escape from legal entanglements likely to result in financial loss or punishment, the desire for sympathy, the escape from distasteful social, domestic, sexual, and occupational relationships.

This vigorous polemic is rich in clinical information and a useful corrective to the pseudo-pathological conceptions underlying such terms as traumatic neurasthenia. Yet it contains elements of danger, and the appearance of "nerves" in the group of pathopleiosis is perhaps correlated with the absence from the bibliography of any reference to recent work on psychopathology. It is novel to read that "in the circulatory system, fainting fits, palpitation, and cardiac pain that is not cardiological, are put forward as distressing features," and to find classified as pathomimesis these well-known symptoms of an anxiety state. This is a author makes this highly significant avowal: "if we had made the concept more embracing, we could easily have included the great majority of the 294 siblings of the patients." Some of the quoted cases of psychopaths and marked eccentrics are hardly convincing. Here are two, of which the first is an example somewhat disturbing for medical readers.

[1] THE LANCET, 1931, ii., 63.

[2] Mellanby, E.: Brain, 1931, liv., 247; see THE LANCET, 1931, ii., 917.

[3] Canad. Med. Assoc. Jour., January, 1932, p. 40.

> "26·66. Male, 41 years old, living in a foreign country. Known as an 'anxious physician' who is constantly in a state of solicitude about his patients."
>
> "30·74. Male, died at 32. Alert and optimistic, a splendid soldier. A heavy drinker who had indulged in alcohol for many years."

This is surely to cast the net widely. By slightly altering, in one direction or another, the line of demarcation between the normal and the "psychopath and marked eccentric," the percentages of the latter could be halved or doubled according to inclination. Too easily may the results of such an investigation depend on subjective factors in the author. They may depend, for instance, on the feelings he entertains towards his teachers and professional elders. If he honours and reveres these in a becoming spirit (as Dr. Bleuler does Prof. Ernst Rüdin) he will be disposed to adopt criteria which will yield such data as will confirm their findings. If, on the other hand, he dislikes them, his drawing of the line will be such as to lead to wholly different results. Or the drawing of the line may be influenced by a desire, conscious or otherwise, to prove or disprove the hereditary nature of mental disorder.

In estimating the significance of genetic factors in mental diseases, the consideration of eccentricities and abnormalities in the ancestors and collateral relatives always plays a prominent part. Though the task is an exceedingly difficult one, it is desirable that an attempt be made by a competent psychiatrist or group of psychiatrists to lay down some sort of distinction between the normal and the abnormal. The line would necessarily be arbitrary, but this would not matter as long as it was definite. Its precise position should be such as to create the simplest possible criteria for the assignment of doubtful cases to one category or the other.

PEPTIC ULCER AND PULMONARY TUBERCULOSIS.

ALTHOUGH an association in the incidence of peptic ulcer and pulmonary tuberculosis has been postulated from time to time for at least three-quarters of a century, its existence has at least as often been both doubted and denied. Mills Sturtevant and L. L. Shapiro[1] conclude that it is the pathologists who have noted an association, while the clinicians for the most part have been sceptical of any connexion between the two disorders. They report an analysis of 7700 necropsies, made at the Bellevue Hospital, New York, among which there were 891 instances of active pulmonary tuberculosis, an incidence of, roughly, 12 per cent. Among the 120 cases with gastric ulcers and scars there were 43 in which the patient had suffered from active pulmonary tuberculosis at the time of death, an incidence of 36 per cent., or three times as high an incidence as amongst those without gastric ulcers. This difference, as it stands, is statistically significant. When the authors reject the cases of healed ulcer as possibly misleading, in that these ulcers may have existed and healed before the onset of the tuberculosis, the significant difference is not materially altered. Looking at the figures from another aspect, they find the in[illegible] of ulcer of the stomach in all necropsies is 1·12 per cent. (86 in 7700), while the incidence of ulcer of the stomach in necropsies showing phthisis is 3·14 per cent. (28 in 891). The difference, 2·02 per cent., is three and a half times its probable error, and therefore significant by the ordinary statistical criterion. An association also is found in other groups of pulmonary and pleural diseases. Searching for a common factor the authors suggest cough. "It is known that vomiting is a cause of gastric erosions. Cough is similar physiologically, is accompanied by marked alterations in intra-abdominal pressure, and may be accompanied by vomiting, if severe and prolonged." The figures are certainly suggestive, but their meaning is by no means easy to grasp. A hospital population is a "select" population; those who die are a "selected" group of those in hospital; those who are submitted to necropsy are still further selected. To interpret the statistics of the post-mortem room is notoriously difficult; to argue from them to the living is dangerous. Possibly the only sound way to solve a problem of this kind is to record the relevant lesions found in a long series of cases in which death was due to accidental causes.

DOSAGE OF X RAYS IN MALIGNANT DISEASE.

SPEAKING at a discussion held by the Section of Radiology of the Royal Society of Medicine on Jan. 15th Mr. W. Mayneord said that, of the various effects of X rays, the ionisation they produce in air seems most capable of exact measurement. Accordingly all measurements of X ray doses should be in terms of the international r unit, and this with advantage might also be extended to radium therapy. The choice of this criterion is the more acceptable, he said, because over a fairly wide range of wave-lengths the absorption of X rays in air runs parallel to their absorption in tissue. Hence it is reasonable to suppose that the measurement of X ray doses in international r units affords a means of estimating their biological effects. From the practical standpoint the frequent measurement of the output of X ray tubes is essential for accurate dosage. When it is realised that the output of the tubes may vary considerably from day to day, the importance of such tests need not be stressed. In radium therapy, too, precise dosage depends on a knowledge of the amount and distribution of radium in each tube employed.

From the medical standpoint, on which Dr. Hernaman-Johnson and Dr. Finzi were the principal speakers, the discussion served to show that very many factors must be taken into account in the treatment of malignant disease. Apart from the determination of the doses of X rays which will be lethal to particular tumours—which is seldom an easy matter—there is the difficulty of deciding how best to cope with metastases, present or future. Because of this disturbing factor there appears to be a sharp difference of opinion about the best method of treatment. On the one hand the gratifying results often obtained by early workers using X ray apparatus of low output have led some to conclude that it is possible to treat malignant disease with some success without having recourse to doses of radiation strong enough to kill the primary growth. The measure of success sometimes attending the use of small doses is partly responsible for the view that the action of X rays is an indirect one, stimulating the patient's resistance to the disease. This idea, coupled with the belief that it is almost impossible to administer lethal

SPECIAL ARTICLES

E MEDICAL ASPECT OF WINTER HEALTH RESORTS AT HOME.

IQUIRY at coastal resorts in the south and west England has revealed the presence there this uary of many who wintered a year ago on one of seaboards of France or Italy, in Egypt or Madeira, still further afield. More intimate inquiry will e revealed further that some at least of them have wed their intention of not doing so again. The riotic motive, even should its springs persist, will carry them through a second winter without the enities to which they have been accustomed. iat is the proportion of these "oncers" it would convenient to the hotel industry to know; for n this winter things are none too prosperous, as a mber of the usual guests have been kept at home immediate lack of money or anxiety for the future. less there is a prospect for the English hotelier another good winter he naturally hesitates to bark on providing expensive attractions. But less some attractions are provided the "oncers" ll not come again—a rather pretty illustration of a cious circle and one that formed the unspoken ckground of the conference (briefly reported our last issue) just held at Paignton on Torbay. he conference was not strictly a medical one—the iairman stated at the outset that local doctors had ken little part in its organisation—but a number of edical delegates were present, among them county ealth officers and representatives of the medical dvisory committee set up at the meeting held at the nstitute of Hygiene on Dec. 9th, 1931, when a statement about winter marine resorts was issued.[1]

The statement referred to the inadequate equipment of many coastal resorts climatically suitable or winter visitors, and this was admitted at the Torbay conference by the recurring emphasis on the eed at every resort of something like a winter garden o provide a social meeting place with varied pportunities of healthful recreation. In an impressive letter which was read to the conference Mr. Cyril Maude said it had always appeared to him that those catering for the urban visitors who sought release in salubrious air and lovely surroundings had never properly reckoned with the increased love of good music and entertainment, or with the growth of a democratic desire for a mixing of the classes in the enjoyment of pleasures and recreations He suggested the levy of a tax on visitors which would entitle them to unrestricted use of a central pavilion for this purpose, and several speakers pleaded for the abolition of certain restrictive legislation. But apart from artificial aids of this kind the feeling was expressed that coastal resorts should not omit to make known and accessible the charms of their own hinterland. Especially in the mild climate of Devon and Cornwall is it possible in winter still to enjoy the many natural interests of the countryside which have turned these counties into a summer playground.

Two resolutions were passed at the conference. One urged the immediate formation of a British Coast Resorts Association on the rather ambitious lines enumerated by Sir Humphry Rolleston at a second meeting held at the Institute of Hygiene on Jan. 11th when Lord Riddell presided. This meeting was not itself unanimous on the need for such an association. Its only immediate outcome was to set up another committee to consider the advisability of forming such an association. The other resolution of the Torbay conference, proposed by the town-clerk of Penzance, advised coastal municipalities to set up their own local committees consisting of all the elements concerned, including the medical profession. The function of such a committee would be first to try to improve the amenities of the locality, and secondly to collect medical information as to its suitability or otherwise for particular kinds of patients or seekers after health.

This proposal, we are satisfied, is of far-reaching importance. It is almost beyond belief that in any resort which depends largely for its prosperity on a regular influx of winter visitors, many of them weary and infirm if not actually ill, there should be no common meeting-ground of doctors, hoteliers, and municipal officers to consider the best interests of their guests and clients. But so it is. We hold no brief for continental methods, regarding it seemly for our own resorts to develop naturally on their own lines, but there can be no question that, wherever claims are made for any locality of health-giving properties, they should be made, as in all important continental resorts, by a consensus of the local medical fraternity; these should meet to consider how far these claims can be justified by medical knowledge and in what way they can best be honoured, appointing spokesmen to keep their views before a local executive committee. Had there been in each resort such a committee of action, the problems of the present winter might have been squarely faced and appropriate action taken. It is clear that some central association will be needed to codify, collate, coördinate, and distribute the information supplied by such local committees. It may be too late in the present season to develop a complete central association, but something might be done to set up a central organisation to serve the medical interests of the health resorts of the whole country. Certainly it is not too late for every coastal municipality to set its own house in order.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

UNDERGRADUATES AND OFFICIAL DUTIES.

THE students' representative councils of the four Scottish universities lately held their annual conference at Edinburgh and were addressed by Sir Thomas Holland, Principal of the University. Sir Thomas said that the student who took no part in the social and athletic activities of his undergraduate body was not worth a degree; but when his share was so great that his academic work definitely suffered he showed a lamentable deficiency in his sense of proportion. For that share he would have to pay a very heavy tax for the rest of his later years. The speaker often worried over the problem of the student who had enforced duties of that kind to carry on. Most forms of recognition of such work would destroy automatically and at once the very value of the experience. The nearest he could imagine to anything like actual notable change from the war-time practice of calling such cases "disordered action of the heart" and setting up special heart hospitals for their study, but to regard them as examples of malingering is equally *fatal to understanding.* Although he pleads that psychotherapy and mental hygiene should have a place in the teaching of clinical therapeutics, yet Prof. Pope's therapy does not seem to have developed beyond the simple principles of assuring the patient that there is nothing the matter with him and then urging him to work. Anyone familiar with the treatment of intelligent "neurotics" knows of the resentment aroused by this method—useful though it may be in selected cases—and even among compensation cases are to be found men whose condition demands informed therapy, which, under present conditions, is unobtainable and in the absence of which they have no alternative but to cling to compensation. With such men the assurance that there is nothing the matter is a direct invitation, almost a compulsion, to produce symptoms that will prove their case. *The stigma attached to* "nerves" is a hindrance to diagnosis and treatment, and Prof. Pope's reference to war cases reminds us how for a time the mental origin of shell-shock was denied as a libel upon brave men. After stern necessity had enforced a correct view, the psychopathologist then had to fight a battle on another front and defend the sufferers against that therapy which would abolish shell-shock by shooting every man that had it. The statement is true that the legal discontinuance of pensionability for the so-called neuroses would probably lead to great economic saving and eliminate a great deal of valetudinarianism, but how would we apply this principle to telegraphists' or writers' cramp ? The answer is already known to the psychopathologist, for the stigma of neurosis has for years prevented us from admitting that these disorders are psychologically determined. The view, now gaining ground, that the compensated disability called miners' nystagmus is largely psychoneurotic would be rightly resisted if Prof. Pope's generalisation represented all that can be offered in the way of understanding and treatment. "Nerves" involve some of the most pressing problems of medicine, and the recognition in a particular case that symptoms do not depend upon physical morbidity is only the beginning of diagnosis, whilst to treat the sufferer from pathological fears or tormenting impulses with doses of optimistic psychology is often the negation of effective therapy. *In industrial cases the granting of compensation* without treatment, or even accurate diagnosis, has brought about a situation that justifies Prof. Pope's warnings as to our share in producing it ; but we must remedy our neglect of psychopathology before we dare exercise moral judgments upon the victims of scoliopathexis.

THE STERILISATION OF WATER BY CATADYN SILVER.

THE problem of sterilisation of water on a scale much smaller than is required by a town's waterworks, and much larger than that of the laboratory, is not an easy one, as those can testify who have had to advise on water-supplies for country houses or small isolated institutions. A process for which great claims have been made—the catadyn process of Herr Krause—has been carefully investigated by Dr. E. V. Suckling, who read a paper on his work at the Public Works, Road, and Transport Congress, held in November at the Agricultural Hall. The process is more or less a secret one ; silver in a finely divided form is somehow dispersed over the surface of sand, which is used as a filtering material for the water to be sterilised, or the silver may be distributed on the inner surface of a vessel in which the water is stored. A very *minute* quantity of silver goes into solution, if indeed this is the proper term, and it is claimed that this small amount, which is of the order of one to six parts per hundred million, will effectually sterilise the water. Dr. Suckling finds that under favourable conditions this claim can be substantiated. The process is slow and delicate, and applicable mainly to waters which are not highly polluted with sulphides, chlorides, iron, or organic matters such as are often found in waters which need sterilisation. It is also costly for use on a large scale. In spite of these drawbacks, which for the present unfit the process for use on the large scale. the entire absence of odour and taste production and the simplicity of the method suggest that it may be found of use in making water fit for drinking when travelling. The catadyn vessels which can be *obtained in this country* might ease the lot of the *continental traveller who,* when he does not wish to drink the wine of the country, is forced to choose between what he fears may be diluted sewage and excellent bottled water costing nearly as much as wine and indistinguishable in taste from good tap water. Dr. Suckling expressly *states that* his experiments, which are fully set out in the paper, were only on the laboratory scale, but they are welcome as affording trustworthy information about an attractive process.

NERVOUS COMPLICATIONS OF GLANDULAR FEVER.

INVOLVEMENT of the central nervous system in glandular fever has not hitherto been suspected but recently two cases have been reported, one from Scandinavia and one from America, that suggest its occurrence. In the first of these, described by A. H. Johansen,[1] the diagnosis does not seem fully established and indeed the only symptom characteristic of glandular fever was a high degree of lymphocytosi associated with the presence of lymphoblasts General glandular swelling, splenomegaly, an other signs were absent. The second case described by G. H. Epstein and M. Aameshek, Th presents a much more typical picture. characteristic blood changes were fully developed there was general enlargement of the lymph glands palpable spleen, and tonsillitis. In both cases th cerebral conditions were present at the onset of th disease, lasted throughout its course, and ended i complete recovery. Their character was that of simple aseptic meningitis associated with excess o lymphocytes in the spinal fluid, and in one of the cases with an increase in its total protein content It is not possible to say whether in these cases th cerebral condition and the glandular fever wer entirely distinct or whether they were both manifestations of the same infection. The latter view which is supported by Epstein and Aameshek, is b no means improbable. Glandular fever is obviousl a generalised infection, and though it mainly attack the lymphoid system the appearance of hæmorrhagi nephritis as a complication of some cases shows tha it can at times involve other tissues. There seem no reason therefore why the central nervous system should not occasionally be involved.

[2] New Eng. Jour. Med., 1931, ccvi., 1238.

particularly in the collection and distribution aman immune serum. In 1928, a similar com- ee was set up in Sydney, under the chairmanship ir Charles Clubbe, who was instrumental in its ıation. This committee is understood to have ıt 5000 c.cm. of human immune serum available. results of the use of the serum in the preparalytic es have been very good.

SHIPS' DOCTORS.

bout a year ago public attention was drawn to the that a man, who had been taken ill on the passage n New Zealand to Australia, had died because re was no surgeon on board the ship to perform an ration. It was stated, at that time, that as the was registered in New Zealand, the matter of king it compulsory for mail steamers to carry tors rested with the Commonwealth authorities l not with the State Government of the port of ival. It has now been announced that the mmonwealth Minister for Transport intends to e action to test the application of the Australian vigation Act to ships registered in New Zealand d trading between the Dominion and Australia. section of the Act requires that a medical man shall carried on every ship proceeding on a voyage of ore than 650 miles, which has 100 or more passengers board. Under protest, the company has placed medical officer on board the ship. It is understood at, in the event of any passenger ship leaving for ew Zealand without a medical officer on board, the ommonwealth Government will immediately institute proceedings against the company concerned.

EPIDEMIC DISEASES AT LORD HOWE ISLAND.

Lord Howe Island, a dependency of the State of lew South Wales, is a boomerang-shaped island, bout seven miles long, lying 450 miles E.N.E. of ydney. The islanders originate from a party of hree white seamen and some Maori women and oys, who reached the island in 1833 and formed the irst settlement. Some of the descendants of these ioneers still reside on the island, the total population of which is about 120. They live on the palm industry, which is conducted on a communal plan, so that each islander will get an adequate living. Only two epidemics of infectious disease are known to have occurred, the first being in 1868, when some of the Pitcairn islanders visited Sydney in the schooner *Pacific*, contracted measles on the return journey and were obliged to call at Lord Howe Island, where the disease broke out after their departure. The second, an epidemic of scarlet fever, thought to have been carried there by a tourist, was in 1929–30. The disease was at first not recognised, for there is no medical practitioner on the island, the medical services being rendered by the schoolmaster's wife, who is a trained nurse. A medical man, who was on a visit with a tourist party, was asked to see some of the sick and immediately recognised the disease as scarlet fever. There were 17 cases, one of which proved fatal.

It is of interest that rats were unknown on the island until 1918, when a number made their way ashore from a stranded vessel. They are causing great damage to the palm industry.

VITAL STATISTICS FOR NEW SOUTH WALES, 1930.

The report of the director-general of public health for New South Wales shows that the birth-rate (20·94 per 1000), the general death-rate (8·54 per 1000), and the infantile mortality-rate (49·72 per 1000 births) are the lowest yet recorded in the State. The low death-rate is attributed to the absence of epidemic diseases of the respiratory system and a decline in deaths from diseases of the heart and from cancer. There were increases in the deaths recorded from measles, enteritis, and gastritis in children, and suicide.

THE HOBART PUBLIC HOSPITAL.

A Royal Commission has just been held to inquire into certain irregularities, and to report on the administration, management, and control of the Hobart Public Hospital. In the summary of the conclusions of a scathing report, it is recommended *that the present system should be replaced by an honorary system, and that an honorary medical staff should be developed. The position of surgeon superintendent, it is proposed, should be abolished, and a medical superintendent should be appointed to direct the medical services of the hospital, the administration of the institution to be mainly in the hands of the secretary.*

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

THE MEDICAL REGISTER OF THE IRISH FREE STATE.

A FEW weeks ago a public health authority in the County Dublin appointed as locum tenens medical officer of a dispensary district a man holding the medical degrees of the National University, and at present occupying a position as house surgeon in England. When the appointment was submitted for approval to the Department of Local Government and Public Health, the Minister pointed out that this practitioner's name did not appear in the Medical Register of the Irish Free State. and that, under the Medical Practitioners' Act, 1927, no one could hold an appointment as physician or surgeon in the Irish Free State under any local authority maintained wholly or partly out of the rates unless his name was on the Register of the Irish Free State. It was announced that the practitioner refused to register in the Irish Free State, and consequently the appointment lapsed. It is curious that nearly five years after the establishment of the Register it should still need to be pointed out that practice as a physician or surgeon may be undertaken in the Irish Free State only by those who are on the Medical Register of that dominion.

THE LÜBECK TRIAL.

(FROM OUR BERLIN CORRESPONDENT.)

(*Continued from p. 164*)

THE PUBLIC PROSECUTOR'S CASE.

THE hearing of witnesses and experts being finished, the public prosecutor began to plead. Nothing in his long legal career had ever, he said, struck him so much as the reading at the beginning of the trial of the names of the 75 infants who died and of the 125 who were injured. Dr. Altstädt, who had introduced the Calmette method, had done so without having had any experience with it in practice and with only some knowledge of the literature. He would not say that he and Prof. Deycke had done intentional injury, but he must maintain that they had acted in a very careless way and should be punished for having caused *death* and injury by neglect. The Lübeck Senate, relying on Dr. Altstädt as their medical adviser, had not recognition was in his own college in London, where they lived a very simple life and it was possible to make a very simple rule. Certain officials of the Union—which corresponded roughly to a students' representative council—were granted an extra year, free of fees, in order that they might not be forced at once to face the final examinations; and possibly in that way to become forced to accept a second class degree, when otherwise, if free of student activities, they might very well have got a first.

On a proposal (from Aberdeen) that the medical curriculum be extended to six years, Sir Thomas said that the limits were not fixed by mental capacity alone, but by economic considerations. Another year would mean increased cost to the student and would be an added financial burden to the university. Both sides would have to be considered.

THE BIOLOGY OF PARENTHOOD.

Prof. James Ritchie, of Aberdeen, gave as his first lecture in the Farquhar Thomson course one on the Importance of the Child and the Value of Parents. Europe, he said, with less than a fifteenth of the land surface of the earth, contained more than a quarter of the world's population. The world's population itself in 200 years has grown from a mere 500 millions to more than 1700 millions, and the threat of this steady expansion was that in course of time the world would have to exhibit a notice, as Sir Arthur Thomson put it, of "standing room only." He illustrated the problems arising out of the relations of parents and offspring in the ascending groups of the back-boned animals, in which there was an increase and specialisation of parental care.

GLASGOW'S EDUCATIONAL PROVISION FOR MENTAL DEFECTIVES.

In a recent lecture, Dr. Arbuckle Brown, deputy medical officer of health and school medical officer for Glasgow, stated that at present there are almost 1800 children in special schools or classes. Some of lower grade are also receiving instruction, but these are in *occupation* centres provided by the after-care special schools' committee. The older children from the special schools are given instruction suitable to their after-school life. The boys are drafted to centres for special trades—carpentry, boot-making, iron work, tailoring, and other occupations, both of trade and educational value. The after-care staff undertakes the supervision and encouragement of the children after they left school at 16. The number so cared for is 1300. The staff visit the homes, encourage the young people to find occupations congenial to themselves, or find places for them and maintain supervision till the staff officer is assured that they have become firmly *established and are doing* useful work. Something like 57 per cent. of the boys were employed, said Dr. Brown, but a lower percentage of the girls. The girls are more useful in domestic work and are often kept at home.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

FREE ADVICE ON MEDICAL PROBLEMS.

IN a recent communication to the Academy of Medicine, Dr. R. Dujarric de la Rivière gave a brief account of a new service which has just been started in Paris. This Consultation Publique et Gratuite d'Hygiène is not a dispensary nor polyclinic where treatment is provided. For treatment, it is expressly insisted, patients must go elsewhere. But in the past they have often found it difficult, and sometimes expensive, to find this "elsewhere," and they have not always found it. Or it has not been of the best—an inevitable sequence to the haphazard ways of the past. The new service brings the public health medical officer in direct touch with individual members of the public. Tracts and pamphlets on general hygiene and special subjects are available, but the special feature of this service is not wholesale advice by pamphlets, but individual consultations at which the public health medical officer acts as guide, philosopher and friend to patients and their relatives It would, perhaps, be misleading to apply to this new service the term "clearing-house," which suggests a highly impersonal machine for sifting morbid material with the help of clerks and secretaries. The service is equipped to give expert advice on the hygiene of housing, food, physical exercises, baths and swimming baths, infant and child welfare, the care of school-children and the aged, the choice of profession, tuberculosis, syphilis, cancer, and alcoholism. Inquirers are told where they can obtain analyses of sputum, &c., what steps to take with regard to disinfection after a contagious disease, where and how they can be vaccinated against typhoid fever and diphtheria, and about the pitfalls of sanitary legislation. It augurs well for the future of this service that its sponsors are very much alive to the importance of its being run by a specialist in public health—not just anyone with a medical degree.

THE PATENTING OF SCIENTIFIC DISCOVERIES.

It will be remembered that a commission was recently appointed by the Academy of Medicine, with Madame Curie as one of its members, to investigate the possibilities and desirability of securing some reward for scientific discoverers by the patenting of their discoveries. Last June Madame Curie drafted a resolution, to which all the other members of the commission subscribed, in which she pleaded the cause of the inventor, urging that protecting his rights would not only be an act of justice to the individual, but would also generally favour the progress of science by aiding laboratories and hospitals and other institutions which serve the public. On Dec. 29th the final conclusion of Madame Curie's draft resolution was adopted at a meeting of the Academy. The text is: "The Academy declares itself in favour of the creation of the rights of the savant and recommends that the recognition of these rights should be hastened by the initiative of the public authorities."

AUSTRALASIA.

(FROM OUR OWN CORRESPONDENT.)

INFANTILE PARALYSIS IN SYDNEY.

THERE are indications that a serious epidemic of infantile paralysis may make its appearance in Sydney during the coming summer. It is not expected to reach its peak until February or March. During the last seven weeks, 52 cases have been reported with nine deaths, and 21 patients are at present under treatment at the Royal Alexandra Hospital for Children. During the epidemic of 1929, there were 241 cases with 29 deaths. In 1930, 30 cases were reported with six deaths. In 1926 a committee was formed in Melbourne with the purpose of assisting in the early diagnosis and treatment of this disease,

CORRESPONDENCE

TUBAL PREGNANCY.

To the Editor of THE LANCET.

,—Were it not for the fact that Prof. Blair Bell to feel that he is not as other gynæcologists, ould feel inclined to let his letter on Mr. Tanner's ted case of tubal gestation lie on the table as st-prandial red herring, rather than reply to is undoubtedly meant to be an educational . As Prof. Blair Bell has given expression to pinion on Mr. Tanner's treatment of his case h would be shared by few, if any, gynæcologists anding, I hope he will not mind answering the wing questions.

Is it sound surgery to conserve a tube in which bal pregnancy has occurred, when the great ability is that this tube was abnormal before the nancy (as is generally believed), and will be even normal after it has been damaged by the nancy?

. What guarantee is there that active chorionic e will not be left in the tube, to cause further ion, as is known to have occurred when the stine has had villi implanted on its surface after ubal rupture or abortion?

. What guarantee is there that large vessels tured in the tube wall, or even raw edges will not tinue to bleed if adequate control of the hæmorge is not secured by removal of the tube?

ne cannot help feeling that if Prof. Blair Bell l but visualise what he has seen and had to contend th in these cases, he will modify the views he has pressed.—I am, Sir, yours faithfully,

AUBREY GOODWIN.

ueen Anne-street, W., Jan. 25th, 1932.

To the Editor of THE LANCET.

SIR,—With regard to Prof. Blair Bell's letter in ur last issue, I did not suggest that the colouration the umbilicus was unknown but that it was rare. personal letters, Dr. J. A. Ryle and Prof. Miles . Phillips refer me to a similar case reported by . S. Cullen in Volume I. of "Contributions to Medical nd Biological Research," New York, 1919, published honour of Osler on his seventieth birthday. Prof. hillips says in his letter:

> "Although I have never seen bluish discolouration of the umbilicus, I have been on the look out for it ever since r. Cullen of Baltimore drew attention to it as a diagnostic ign."

Prof. Blair Bell criticises removal of the ampullary portion of the ruptured tube containing the pregnancy. This was done because it was the only quick and safe way of arresting hæmorrhage which had filled the abdomen with blood. Quite apart from the loss of time, removing the pregnancy alone is attended with the risk of leaving behind chorionic villi which might erode the tube or other structures such as the omentum or intestine and cause fresh hæmorrhage. Further, I suggest that such a damaged tube, if it functions again, may give rise to a second ectopic pregnancy.

Both ovaries and the left tube remained after the operation, so that my procedure was not drastic. I hope the patient does not have an ectopic pregnancy in the left tube—an event I have met with on several occasions.—I am, Sir, yours faithfully,

W. E. TANNER.

Queen Anne-street, W., Jan. 23rd, 1932.

BRILLIANT GREEN FOR SYCOSIS.

To the Editor of THE LANCET.

SIR,—Your annotation on this subject will be read with much interest. I should, however, like to state that in my hands, and in those who have adopted my plan or method, the treatment of coccigenic sycosis is neither intractable nor prolonged. Another fallacy is that this form of sycosis is liable to recur after it has been properly cured. In my experience the cure remains permanent. But, as the whole process of the disease is under complete control by correct applications, sufferers have no anxiety. The alcoholic treatment has been advocated and carried out by me during many years. Alcohol is the chief active agent in the antiseptic use of tincture of iodine, picric acid, and largely in Prof. Senin's use of brilliant green as it is in mine. One can hardly understand anyone applying disfiguring pigments to the face when pleasanter methods are available. Alcohol is a mild flocculent of proteins, either of the skin tissues or of the organisms with which it may be infected. Further, it is a powerful dehydrator, a quality highly prejudicial to the vitality of the cutaneous flora. These two activities make it the ideal antiseptic for the skin, to which it can be applied frequently without injury. Its value in sycosis depends entirely upon the oft-repeated statement of Sabouraud—that sycotic abscesses are comparatively superficial. Thus they can be reached by readily diffusible and volatile liquids.

The details of the method I adopt and advise will be found in a paper I read before the then called London Dermatological Society and later published under the title of Some Auto-infections (*Clinical Journal*, March 9th, 1921, pp. 145–150). The matter has been recently communicated to the *Dermatologische Wochenschrift* (1930, xci., 1873).

I am, Sir, yours faithfully,

Wigan, Jan. 23rd, 1932. R. PROSSER WHITE.

VACCINE TREATMENT IN INFECTIVE ARTHRITIS.

To the Editor of THE LANCET.

SIR,—In her interesting communication on this subject in your last issue (p. 178) Dr. Phyllis Congdon draws no distinction between the cases treated with stock and autogenous vaccines respectively and the proportion of each group is not given. As no details are given as to bacteriological tests of the patients on admission, it would appear that the diagnosis of *infective* arthritis was made on clinical grounds only. Furthermore, as the stock vaccine employed contained no fewer than 40 strains of streptococci, the dose of any microbe that might be present in the system of the particular patient would be very small indeed. And as it was only prepared once a year the probability is that, by the time it was received by some patients, much of its original potency would have been lost. Many pathologists would not expect a stock vaccine of this type to be very useful. Dr. Congdon gives only the initial dose of any vaccine; the dose attained is also of importance. Only streptococci are mentioned. The fact that dual or multiple infection is commonly present in arthritis is an important factor in its vaccine therapy.

I submit therefore that, even within the limits of her inquiry, the conclusion that "vaccines do not insisted on consulting the German Health Office before introducing the method in Lübeck. When Dr. Altstädt was asked at the trial whether he did not know that certain physicians in Germany and abroad had warned against an indiscriminate application of B C G he had replied that those physicians were of no importance in the medical world. He (the public prosecutor) must however state that one physician expressing doubt on the harmlessness of a remedy must be heard as much as a hundred others believing in it. Dr. Altstädt's omissions were (1) that he had neglected to ask the opinion of those who had had some experience with B C G, e.g., Prof. Prausnitz; (2) that he had not insisted on having the B C G cultivated in a special laboratory as expressly prescribed by Prof. Calmette; (3) that he had not tested the method in animals before introducing it in patients; (4) that he had not provided for a thorough observation of the infants.

Turning to Prof. Deycke, the public prosecutor said that after it was decided to introduce the Calmette method its danger was further increased by the condition of Prof. Deycke's laboratory. The majority of medical experts had given their opinion that the B C G had not become virulent but that the cultures were contaminated in Lübeck by tubercle bacilli. The question whether B C G might become virulent could not be decided by a law court but only by medical science; in his opinion however the evidence they had heard was sufficient to establish that, in this particular case, a contamination of the cultures had occurred in Prof. Deycke's laboratory. It was not clear whether Prof. Deycke or one of his assistants had made the mistake, but Prof. Deycke must be held responsible for the work done in his laboratory, especially as he had allowed a cultivation of B C G in the same room as other dangerous bacilli. Prof. Klotz must be held guilty because he had not done his duty in observing the infants within and without the hospital. The public prosecutor asked for a verdict of guilty against Dr. Altstädt and Prof. Deycke with a sentence of three years' imprisonment, against Prof. Klotz with a verdict of one year's imprisonment, and a verdict of not guilty in the case of Nurse Schütze, the charge against whom had not been proved.

Counsel for the parents said he did not, on their behalf, make any financial claim against the accused medical men, the Lübeck Senate having agreed to pay for all the damage done by the disaster. Other cities which had sent expressions of sympathy to the city of Lübeck should contribute to the expense because they had been preserved from similar disaster by the Lübeck experience. The negligence of the accused was that they believed that B C G was a virus fixe without considering the opposite views of other medical men. That opinion, though formed bona fide, should not protect them against a charge of manslaughter by neglect and a sentence of imprisonment.

THE WEEKLY RETURN.

It would be ungenerous not to acknowledge with gratitude the improved format of the Registrar-General's Weekly Return which came into being with the issue for the week ended Jan. 9th. It is just ten years since any change was made; the cover remains unaltered, but there are within many changes in type and arrangement which will make the return readier for reference, although at the moment any change may be found a little perplexing. The figures are now based on the existence of 117 instead of 1[illegible] great towns. The chief addition is to be seen in two new tables on page 3, one of which gives the annual death-rates in four recent weeks for London and 1[illegible] representative great towns as well as for the whole 117 great towns, and for six grouped areas. The other is a new table of total notifications of four principal infectious diseases showing their actual number and the expected number based on the median value of the corresponding weeks of 1923-31. From this table it will be seen at a glance that in the week ended Jan. 16th the notifications for scarlet fever, diphtheria, and enteric fever in England and Wales were 16, 14, and 16 per cent. respectively below expectation, whereas for primary pneumonia they were 44 per cent. in excess of expectation. Table 3A is another small addition giving corrected totals for England and Wales of notifications of infectious disease for the previous week, together with returns too late for inclusion in Table 3. In Table 3 itself the number of notifications for the administrative county are now given in cases where the population of county boroughs has to be deducted from that of the geographical county. Moreover, for the first time, municipal boroughs are distinguished from urban districts—a great convenience. One table has been allowed to drop out altogether; but as it has long had an archaic flavour it will not be missed except by the seeker after abstruse knowledge who wanted to know the number of stillbirths in Warsaw or the deaths from whooping-cough in Rio de Janeiro. The price of the Weekly Return remains unaltered at sixpence, and we commend it once again to the continuous study of all whose duty or hobby it is to form an accurate idea of the current health of the country.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JAN. 16TH, 1932.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 68 (last week 68); scarlet fever, 1493; diphtheria, 956; enteric fever, 27; pneumonia, 2210; puerperal fever, 44; puerperal pyrexia, 120; cerebro-spinal fever, 50; acute poliomyelitis, 4; encephalitis lethargica, 14; dysentery, 21; ophthalmia neonatorum, 94. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Jan. 19th–20th was as follows: Small-pox, 133 under treatment, 2 under observation (last week 115 and 2 respectively); scarlet fever, 1223; diphtheria, 1452; enteric fever, 7; measles, 758; whooping-cough, 360; puerperal fever, 17 (plus 11 babies); encephalitis lethargica, 225; poliomyelitis, 2; "other diseases," 288. At St. Margaret's Hospital there were 22 babies (plus 13 mothers) with ophthalmia neonatorum.

Deaths.—In the 117 great towns, including London, there were no deaths from small-pox, 2 (0) from enteric fever, 53 (22) from measles, 10 (2) from scarlet fever, 46 (10) from whooping-cough, 33 (7) from diphtheria, 56 (12) from diarrhœa and enteritis under two years, and 412 (145) from influenza. The figures in parentheses are those for London itself.

The fatal cases of enteric fever occurred at Eastbourne and Sunderland. Ten deaths from measles were reported from Stoke-on-Trent, 4 from Manchester, 3 each from Portsmouth and Bolton. Birmingham reported 10 deaths from whooping-cough, Liverpool 7. Of deaths attributed to influenza Birmingham stood highest with 17, followed by Manchester 14, West Ham 12, and Bradford 11.

The number of stillbirths notified during the week was 284 (corresponding to a rate of 42 per 1000 births), including 51 in London.

THE PREVENTION OF DEAFNESS.

To the Editor of THE LANCET.

,—In Dr. Sorsby's paper in your issue of 16th there is an allusion to the Zünd-Burguet ment which is neither fair nor correct. Dr. by says that in treatment "the many efforts, such the Zünd-Burguet apparatus, which aim at lucation, are of no value." A perusal of my hand- on the electrophonoide method or any of my ished cases would have made Dr. Sorsby hesitate re making so sweeping a statement. The following s of deaf children are selected because they have kept their improvement for at least four (in some) years after being pronounced "incurable" by itable otologists.

Boy, 10; catarrhal deafness. Whisper, 14 in. before; after treatment.

Boy, 8; also catarrhal. Voice before treatment, 30 in.; , 17 ft.

Boy, 8; catarrh following measles, with concomitant s of commencing internal ear deafness. Whisper, 45 in. re; 15 ft. after treatment.

Boy, 7; toxic deafness; internal ear type; after ic wound of leg. Voice before treatment, 15 in.; r treatment, 15 ft.

ese children were all ordered for deaf-schools, and now doing well at different well-known public ools. A fifth boy, whose hearing was reduced by st-suppurative processes to R. 1 ft., L. 3 ft., was proved by 5 ft. and 10 ft.

Dr. Kerr Love and I have for nearly 30 years eached consistently the prevention of deafness, and is a great satisfaction to us that our lead is now ing followed by a younger generation. To me, rsonally, it is a matter of pride that what Dr. rsby says in his paper confirms a great deal of hat I stated in THE LANCET in 1912, the *British urnal of Children's Diseases* in the same year, the *ugenics Review* in 1914, the *Practitioner* for 1915, d the *Journal of Laryngology* in 1917.

I am, Sir, yours faithfully,

MACLEOD YEARSLEY.

Harley-street, W., Jan. 20th, 1932.

CANCER OF THE LUNG.

To the Editor of THE LANCET.

SIR,—Among the annotations in your last issue see one on primary carcinoma of the lung, in which note the following observation: "If more space in the literature on bronchial carcinoma were given to diagnosis, especially early diagnosis, and less on histogenesis and metastases, the average medical reader would be grateful." There follows an account of recent clinical observations by Dr. B. M. Fried which are described as adding one new idea of importance. The writer of the annotation does not appear to be aware of the prominence given to this very aspect of the subject in Dr. Maurice Davidson's book on "Cancer of the Lung," to which, unfortunately, no reference is made. Apart from the fact that it is the only book on this subject that has been published in the English language, and that it deals with the subject mainly from the clinical and diagnostic point of view the omission, if I may say so, seems to me the more surprising since I note the volume was reviewed by THE LANCET on Nov. 15th, 1930. In view of the appeal in this annotation for practical information to meet the demands of the average medical reader, I do feel that attention should be drawn to a standard work on the subject in question.

I am, Sir, yours faithfully,

Harley-street, W., Jan. 24th, 1932. PHILIP ELLMAN.

NEMBUTAL AND CHLORAL IN CHILDBIRTH.

To the Editor of THE LANCET.

SIR,—With reference to the paper in your issue of Jan. 16th by Drs. O'Sullivan and Craner on the use of nembutal and chloral in 60 cases of childbirth at the London Hospital, I would like to make a few confirmatory statements. I have given nembutal (alone) to 18 of my parturition cases with most pleasing results. I was giving three ampoules, but now give four (easily swallowed by most patients) when the os is three-fifths dilated, or when labour is obviously in the second stage. Within 15 to 30 minutes the patient is asleep between the pains; she groans during pains, which are not lessened in frequency nor strength; in fact, in the case of two very nervous patients, my sister-in-charge of the maternity ward and I thought that the pains became more powerful under the nembutal. Labour progresses normally, and the child cries lustily when born. The patient usually sleeps for five or six hours after the child is born, and has no memory of the birth. One of my earliest cases under nembutal very greatly impressed us; when asked next day how she felt after taking the drug, and whether she had pain, she said she felt no pain, but she "felt stronger and could feel the child coming down and out." In two cases of unreduced occipito-posterior presentation and one case where the head remained transverse, ether was used while I rotated the head, and extracted with forceps, and less anæsthetic was needed than if nembutal had not been given. The puerperium in all these cases has been normal, and children healthy. It appears to me that in nembutal we have a drug which should help the general practitioner and be of great comfort to all women in childbirth.

I am, Sir, yours faithfully,

J. W. LANE,

Hilsea, Jan. 26th, 1932.
Major, R.A.M.C.; Officer Commanding, Military Families' Hospital.

MODERN HOSPITAL CONSTRUCTION.

To the Editor of THE LANCET.

SIR,—I was glad to see your comments on modern hospital construction in a leading article last week. The sanitary tower with cross-ventilated lobby was not an unmixed blessing; too often the cross ventilation was too much for the patients and staff, and the multiplicity of doors was a nuisance to the nurses carrying bed-pans to the sink room.

The experiments in balcony construction which you describe in French and German hospitals are most interesting, but the continuous balcony in front of ward windows is costly to construct, and except in special cases not always a success in the English climate. I found when visiting a well-known sanatorium in the south of England recently that the patients were not allowed by the medical staff to lie out in the sun, and the balconies were therefore of very little use. The proportion of window to wall space in the ward also requires careful consideration. The feeling of comfort and protection so important to a sick person may be lost if the ward is designed like a glass box, though large windows to the south are nearly always an advantage.

When I was a patient in a hospital during the war I was amused at the continual struggle that went on between the staff and the patients with regard to the open window. We must try to bear in mind that a draught may cause a patient intense annoyance, and appear to hold out any better prospect of improvement or cure of infective arthritis than the other methods of treatment in use" is not justified by the evidence given. It has little or no bearing on the value of autogenous vaccine therapy based on complete bacteriological examination of each individual patient.

I am, Sir, yours faithfully,
A. KNYVETT GORDON.

Bedford-square, W.C., Jan. 23rd, 1932.

FILLING UP A DEATH CERTIFICATE.

To the Editor of THE LANCET.

SIR,—As a medical officer of health I have to scan the weekly returns of deaths sent to me by the local registrars, the causes of death being compiled from the death certificates furnished by medical practitioners. Judging by the returns which come to my notice, it would appear that doctors have difficulty in allocating the causes of death as between primary and secondary causes. In this respect there seems to be no difference between those recently qualified and those who have been in practice many years. It should not be difficult to fill up a death certificate correctly if it is borne in mind that what is meant by a "primary" cause of death is the disease, present at the time of death, *which initiated the train of events leading thereto*, and not a mere secondary, contributory, or immediate cause, or a terminal condition or mode of death.

Here are a few instances of gross error which have come to my notice:—

1. Primary cause, cardiac failure. Secondary, aortic disease.
2. Primary cause, hæmatemesis. Secondary, cancer of stomach.
3. Primary cause, exhaustion. Secondary, cancer of bladder.
4. Primary cause, heart failure. Secondary, cancer of breast.
5. Primary cause, exhaustion. Secondary, pulmonary tuberculosis.

I could continue this list indefinitely, but I think I have made it clear that more attention should be paid to teaching the medical student the right way to fill up a death certificate, and I hope the teachers of public health and administration will make a note of this if they have done me the honour to read my letter.

I am, Sir, yours faithfully,
A. B. DUNNE, M.B. Camb.

Doncaster, Jan. 22nd, 1932.

ERYTHROCYTE SEDIMENTATION TEST.

To the Editor of THE LANCET.

SIR,—An annotation in your issue of Jan. 9th refers to the erythrocyte sedimentation test as an index of the activity of rheumatic infection. I have performed this test in some thousands of cases since Fahraeus sent me a copy of his book in 1922, and readings are given in all those reported in my three volumes of the "Nature of Disease" wherein also the rationale of the test is described. My conclusion is that, as rapid sinking of the red blood corpuscles runs pari passu with active dehydration of the protein particles, and as this chemico-physical change may be brought about by physical agents, chemical poisons, and micro-organisms, the test has no specific value and cannot be employed to determine if a particular organ in the body is being attacked by the invader responsible for the dehydration. Nor can it be used to ascertain when the invader ceases to be active, first, because continued activity tends to cause hydration, and secondly, because months may elapse after the invader has vanished before the reading becomes normal. Hydration checks the sedimentation of the red blood corpuscles. The test depends primarily upon the chemico-physical state in which the protein particles of the plasma happen to be and not upon the number of the red blood corpuscles or the protein content of the plasma. The suspension stability of the red blood corpuscles is reduced only in those cases of anæmia where the protein particles are being subjected to dehydration, the state in which the red blood corpuscles happen to be does not influence it. In aplastic anæmia the sedimentation rate is not increased, and in pernicious anæmia where it is the red blood corpuscles do not fall so fast as they do in streptococcic septicæmia, except just before death.

I am, Sir, yours faithfully,
J. E. R. McDONAGH.

Wimpole-street, W., Jan. 21st, 1932.

THE MIND IN TUBERCLE.

To the Editor of THE LANCET.

SIR,—In the paper by Dr. Andrew Morland with this title in your last issue (p. 176), I am particularly interested in his reference to the work of Dr. H. Banister at Papworth. Impressed by the lack of treatment in sanatoria on the psychological side, I was fortunate, some years ago, in securing the services of Dr. Banister, who is lecturer in experimental psychology at Cambridge, and whose work in our psychological clinic has been of great benefit to certain of our patients. I am convinced that Dr. Morland is right when he states:

> "In this struggle between health and disease the min plays an important part, and I believe that further understanding of the mechanism by which the mind respond to the stimulus of the disease would enable more rationa and effective treatment to be applied."

Dr. Banister, whose experience in the teaching o psychology to medical students in Cambridge i considerable, would, I am sure, agree with me that knowledge of psychology is of the utmost importanc to those whose work lies in the tuberculosis field, an as Dr. Morland so well puts it: "If the tuberculosi physician could learn so to influence the minds of hi patients that they acquired a proper attitude toward the disease, the greatest therapeutic advance of th century would have been achieved."

I am, Sir, yours faithfully,
PENDRILL VARRIER-JONES.

Papworth Hall, Cambridge, Jan. 23rd, 1932.

RUPTURE OF THE ADDUCTOR LONGUS.

To the Editor of THE LANCET.

SIR,—In his Robert Jones Essay on injuries o tendons and muscles, Mr. H. C. Edwards deprecate (THE LANCET, Jan. 9th, p. 70) immediate operativ treatment of rupture of the adductor longus. Thi leads me to record the following case. A rupture the adductor longus was sustained while playing pol The gap in the muscle was easily palpable, bein rather more than two fingers' breadth in extent Operation was carried out on the following day, an the lesion, which was situated below the pubi attachment, retained by suture. Apart from thre weeks' rest in bed no after-treatment was carried out The injury was sustained in May, in August hors exercise was resumed, and in October racing and polo

I am, Sir, yours faithfully,
LAURENCE O'SHAUGHNESSY.

Berlin, Jan. 21st, 1932.

Infirmary and physician to the Children's ary when he was sent to the south coast with nosis of general miliary tuberculosis and a few s to live. Fortunately he had the will to r. and his experience of tubercle in his own person his advice doubly valuable both to his patients to his professional colleagues. He became sian to the Royal National Sanatorium at emouth, and referee to the National Hospital onsumption at Ventnor; whilst he held appoint- s of a more general character at the Lymington District Cottage Hospital and the Swanage alescent Home for Children. His practice d him widely through the four counties of pshire. Dorset. Wilts, and Somerset, and it haracteristic of him that at 75 years of age he still meeting the large physical demands made im by a wise economy of time, while in the nce of real illness or distress of mind it is on d that his charm and kindliness knew no bounds. ad long been the senior member of the profession ournemouth, and his colleagues recognised in him rn teacher, one with whom it was impossible to or even a few minutes without learning something. ember of the College of Physicians by examination 889. he was honoured 33 years later by election e Fellowship.

e is survived by his widow, a son and three ghters.

MEDICAL NEWS

iversity of Oxford.

n examination for a *Radcliffe Travelling Fellowship* of annual value of £300, and tenable for two years, will begin he University Museum on Feb. 23rd.

andidates must have passed all the examinations required the degrees of B.A. and B.M., and must not have exceeded years from the time of passing the last examination required the B.M. degree. The successful candidate must declare that ntends to devote himself during his tenure of the Fellowship he study of medical science and to travel abroad with a view hat study. In the examination, papers will be set in physio- y, pathology, and preventive medicine, and a subject will proposed for an essay. There will also be a practical examina- n in pathology. Candidates may offer in addition a special nch of either medicine or surgery. Application must be made proper form to the Regius professor of medicine by Feb. 10th.

The *George Herbert Hunt Travelling Scholarship* is awarded thout examination every second year to a graduate in dicine of the University (of either sex) who has not ceeded five years from the date of passing the final amination for the degree of B.M.

The scholarship is of the value of £100, or such smaller sum two years of the income of the Fund provides. Candidates ust undertake to travel abroad for a period of not less than ree months for the purpose of clinical study or research in edicine. Preference is given to those who express an intention becoming surgeons or general practitioners. The next lection will be made in April, 1932, and candidates must send eir applications to the Dean of the Medical School on or before eb. 23rd.

Schorstein Research Fellowship in Medical Science.—The oard of the Faculty of Medicine is prepared to make an lection to this Fellowship in June, 1932. The board has ower, if in special circumstances it shall seem desirable, to ivide the Fellowship into two Studentships.

The Fellowship, which may be divided into two studentships, which will be of the value of £200, will be tenable for two years from Oct. 1st, 1932, in any of the medical departments at Oxford. Candidates must be graduate members of the University, holding a registrable medical qualification, and must be under 35 years of age on Oct. 1st. Application must be made in proper form to the Dean of the Medical School, not later than May 2nd.

University of Glasgow.

The *Harry Stewart Hutchison Prize* of the value of about £50, for the best writing or writings embodying original research work in a branch of medical science relating to children, will be awarded in 1933. Medical graduates (of not more than ten years' standing from their first graduation in medicine) of all British, home, and colonial universities, may be competitors. Particulars will be found in our advertisement columns.

University of London.

A ceremony for the installation of the new Chancellor, the Earl of Athlone, K.G., and for the conferment on him of the honorary degree of Doctor of Laws, will be held at the University of London on Feb. 18th, at 8.30 for 9 P.M. Members of Convocation who desire to be present are asked to communicate with the Clerk of Convocation at the University of London, South Kensington, at latest by Feb. 4th. If it is found impossible to accommodate all applicants, invitations will be issued according to priority of application.

At a meeting of the Senate on Jan. 20th the title of professor of biochemistry was conferred on Mr. Robert Robison, D.Sc., F.R.S., of the Lister Institute; and the title of reader in biochemistry on Mr. J. M. Gulland, D.Sc., and Mr. William Robson, D.Sc., of the Lister Institute and King's College respectively.

The Osler Club.

At a meeting of this club held in London on Jan. 22nd, Mr. S. J. L. Taylor read a paper on Samuel Pepys and Medicine, and Dr. W. R. Bett made a short communication on Viktor Hensen, who in 1856 discovered the glycogenic function of the liver independently of Claude Bernard.

Royal London Ophthalmic Hospital.

The annual dinner of past and present students of this hospital will be held at the Langham Hotel, Portland-place, on Thursday, Feb. 11th, at 7 for 7.30 P.M., with Sir William Lister in the chair. Application for tickets should be made to Mr. Rupert Scott, 70, Harley-street, W.1.

Pharmaceutical Society of Great Britain.

At a meeting to be held at 17, Bloomsbury-square, W.C., at 8.30 P.M, on Tuesday, Feb. 9th, Dr. H. E. Archer will speak on Biochemistry, Chemical Pathology, and Pharmacy.

National Hospital, Queen-square.

Post-graduate lectures and courses are now beginning at this hospital, and will continue until the middle of March. Particulars may be had from the Dean of the Medical School.

The Duke of Connaught and St. Thomas's Hospital.

On Jan. 18th the Duke of Connaught completed half a century as President of St. Thomas's Hospital.

Glasgow Victoria Infirmary Deficit.

A deficit of £26,748 is reported upon the last year's working. Since the paying patients' ward of 32 beds was opened nine months ago it has been fully occupied, and more than 500 cases have been treated.

Billericay Public Assistance Hospital.

An extension of this Essex hospital was opened last week. The cost has been £4000, and there are now 70 beds and accommodation for a staff of 40.

Village Settlement for Cripples.

On Friday last week Prince George visited Shropshire and laid the foundation-stone of the Derwen Cripples' Village Settlement at Gobowen, and opened the Cripples' Training College. He afterwards laid another foundation-stone to commemorate the reconstruction of the Shropshire Orthopædic Hospital adjoining. Beginning at Baschurch 31 years ago with three crippled boys and one crippled girl, the work of the hospital and training college has increased until it covers the counties of Salop, Hereford, Chester, Denbigh, Flint, Montgomery, Radnor, and Merioneth. The hospital now has 320 beds; its trained orthopædic nurses are working in many parts of the country and abroad; its after-care department has charge of between 4000 and 5000 cases, and has 34 orthopædic clinics scattered over the eight counties mentioned.

Fellowship of Medicine and Post-Graduate Medical Association.

Arrangements for next week will be found in our Medical Diary. Forthcoming special courses include one on ante-natal treatment, to be given by Dame Louise McIlroy at the Royal Free Hospital, on Fridays at 5 P.M.; one on diseases of the chest at the Brompton Hospital, all day from Feb. 8th to 13th; one on medicine, surgery, and the specialties, at the Prince of Wales's Hospital, Tottenham, all day from Feb. 15th to 27th; and one on clinical surgery, at the Royal Albert Dock Hospital on Saturdays and Sundays for two week-ends, Feb. 20th–21st and 27th–28th. An evening course for the M.R.C.P. examination, including six clinical and two pathological evenings, four lectures, two ophthalmic demonstrations, and one laboratory demonstration, will be held from Feb. 22nd to March 18th. Syllabuses may be had from the Fellowship at 1, Wimpole-street, London, W.1.

as far as possible a ward should be planned to give each patient a window so that the ventilation can be arranged to suit individual cases.

I am, Sir, yours faithfully,
L. G. PEARSON, F.R.I.B.A.

Knightsbridge, S.W., Jan. 26th, 1932.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdrs. V. F. Walsh, to *Bideford;* and W. P. E. McIntyre to *President*, for Medical Dept., Admiralty.

Surg. Lts. T. B. Lynagh to *Hastings*, C. H. Birt to *Victory*, for R.M. Infirmary, Portsmouth, and G. D. J. Ball to *Vindictive*.

ROYAL ARMY MEDICAL CORPS.

R. E. Gordon is granted a temp. commn. in the rank of Lt.

TERRITORIAL ARMY.

R. Woodside (late Offr. Cadet, Glasgow Univ. Contgt., Sen. Div., O.T.C.) to be Lt.

ROYAL AIR FORCE.

P. J. C. Keane is granted a non-permanent commission as a Flying Officer.

DEATHS IN THE SERVICES.

Surg.-Gen. Sir Henry Hamilton, K.C.B., I.M.S. (retd.), who died on Jan. 22nd at the age of 81, was the son of William Hamilton, of Coolaghey House, Raphoe, Co. Donegal, and was educated at Royal School in that town. Subsequently he entered the Royal University of Ireland, and in 1875 graduated at Queen's College, Belfast, in medicine and surgery. In the following year he entered the I.M.S., and in 1878–80 took part in Roberts' march from Kabul to Kandahar, and was at the battle of the latter place (mentioned in despatches); he was also senior medical officer to General Gatacre's brigade in the Relief of Chitral Expedition, and held a similar office in the operations in connexion with the Frontier risings of 1897–98 (mentioned in despatches and promoted Brigade Surg. Lt.-Col.). In the Boxer Expedition, 1900–1901, he was principal medical officer in charge of No. 2 General Hospital. He received the C.B. in 1904, and was promoted to K.C.B. in 1913.

Major-General Harold Hendley, C.S.I., I.M.S. retd., who died on Jan. 21st at the Thatched House, Caxton, Cambridge, in the seventy-first year of his age, was the son of the late T. Hendley, and received his early education at St. John's College, Hurstpierpoint. Later he studied medicine at St. Bartholomew's Hospital, and qualified with the M.R.C.S. Eng. in 1882. He entered the I.M.S. two years later, having in the meantime taken the L.S.A. At Netley he was Director-General's prizeman in pathology. He saw active service almost immediately, for he commanded the field hospital with the Suakin Expeditionary Force in 1885 (medal and Khedive's star), while in 1886–87 he was medical officer to the 7th Bengal Cavalry with the Burma Field Force (medal and clasp). Successively civil surgeon in the Punjab and at Simla he afterwards became medical adviser, Patiala State, and was D.D.M.S. in India from 1911 to 1915, in which latter year he officiated as D.M.S. Afterwards he acted as Inspector-General of Civil Hospitals and Sanitary Commissioner, and he was a member of the Legislative Chamber, Punjab. In 1917 he was acting D.G., I.M.S., and in the following year D.D.M.S. 4th (Quetta) Division, and Baluchistan Field Force (medal and clasp, and mentioned in despatches). He was awarded the C.S.I. in 1920. Major-General Hendley, who was a graduate of Durham, was an honorary surgeon to the King and an hon. associate of the Order of St. John of Jerusalem.

DONATIONS AND BEQUESTS.—The late Mrs. Matilda Helen Stewart Forbes Murray Rezin, of Old Aberdeen, among other bequests left £2000 to the Aberdeen Royal Infirmary for the endowment of a "Matilda Murray Bed"; £2000 to the Royal Aberdeen Hospital for Sick Children, for the endowment of a "Matilda Murray Bed"; £2000 to the University of Aberdeen, to endow a bursary or bursaries for students in the Faculty of Science; £500 each to the Aberdeen Asylum for the Blind, and the Morningfield Hospital, Aberdeen; £400 to the Aberdeen Dispensary and Vaccine Institution.—An anonymous donor has offered to provide £61,500 towards the cost of a new infectious diseases hospital for Wakefield.

OBITUARY

ROBERT HENRY TODD, M.D. Dub., F.R.C.S. Irel

Dr. Robert Todd, who died on Dec. 14th, at th age of 72, shortly after his return to Australia from England, will be remembered chiefly for his outstanding service in the organisation of the British Medical Association in Australia, and especially in New South Wales. He was born in London in Burlington-street, where his father, Dr. Armstrong Todd, was in practice. From schooling at Christ's Hospital he proceeded to Hertford College, Oxford, and thence to Dublin, where he graduated, and also took the diploma of State medicine in 1886. After gaining his Irish Fellowship in the following year he married, went out to Australia, and set up in practice at Maclean, Clarence River. An old injury to his wrist made it difficult, however, for him to carry on his work, and later he relinquished it and went to Sydney, where he graduated as LL.B., and was admitted to the Bar in 1894. After this he held a number of city appoint ments, including that of city coroner. In 1 he was elected a member of the Council of th New South Wales Branch of the British Med Association, and from 1908 was honorary of the branch, to which he gave almost the whol of his time until April of last year. He also acted honorary secretary for the British Medical Assc tion in Australia, and for his signal services was 1923 presented with a gold medal. He was ciated with the University of Sydney for 20 ye as lecturer in medical jurisprudence and in the of medical practice.

DR. R. H. TODD.

Among many other activities Dr. Todd honorary secretary of the Sydney Amateur C and was a member of the Taronga Park Tru (the Sydney zoological gardens), in which he wa keenly interested, and to which he rendered valuabl service. A man of great, untiring energy and kindl disposition, he was widely known and esteemed, an his helpfulness was especially manifested to th younger members of the profession who sought h advice and guidance.

EDWIN HYLA GREVES, M.D.Edin., F.R.C.P.I

THE death of Dr. Hyla Greves on Jan. 12th lea a gap in the Bournemouth medical circle which ma be hard to fill. Dr. Greves was educated at Shrew bury and Edinburgh University, and had alrea made his mark at Liverpool as pathologist to th

NOTES, COMMENTS, AND ABSTRACTS

POST-VACCINAL ENCEPHALITIS:

S ASSOCIATION WITH VACCINATION AND WITH POST-INFECTIOUS AND ACUTE DISSEMINATED ENCEPHALITIS.

BY PROF. RICARDO JORGE,
ESIDENT OF THE PUBLIC HEALTH COUNCIL OF PORTUGAL.

(*Concluded from p. 219.*)

HE virus of our hypothesis is one which only nges its character of inertia and harmlessness er stimulus by the vaccine virus; apart from this act there is no evidence of its mysterious existence. ht it not at least be possible to catch a glimpse some other forms of its activity apart from cination? Its existence would then come out of region of theory and begin to be apparent.

erebral complications of such infectious diseases ruptive fevers, small-pox, measles, and chicken-pox e been long known to classical medicine. Vaccinia ming part of this exanthematic group, it was ural to confront all these forms of encephalitis ether. Under the impetus of the questions raised the nervous sequelæ of the Jennerian inoculation, se cases were no longer looked at as mere clinical idents, but as documents through which a problem comparative pathology could be elucidated. It is England that the greatest progress has been made th the endeavour to bring these forms of encephtis together. Dr. J. Hutchinson, secretary of the lleston Committee, has tabulated the cases brought his knowledge and has kindly placed at our sposal, together with other useful information, e accompanying Table of fatal cases notified since 27. Moreover, earlier literature dating back long fore the advent of post-vaccinal encephalitis has ready also produced some important contributions.

Are these so-called post-infectious types of cephalitis the same as the post-vaccinal? To firm it on the grounds of clinical similarity alone ould be dangerous; the basis of their identification anatomopathological. Histological examination s shown the identity of lesions in the nervous ssues affected; they present the same Perdrauouman seal as vaccinal encephalitis. This is the athognomonic test, and in face of it the only ses which one ought to consider as definitely roved are the recent ones which have been submitted the test of the microscope.

Encephalitis Post Infectionem.

MEASLES.

Measles, the commonest of the group of exanthematic diseases, has provided the largest number of xamples. The first known case goes back to 1790 Lucas, cited by Greenfield[25]). Fresh cases are ollected day by day, but it is difficult to decide if ncephalitis after measles is in fact becoming more ommon or whether practitioners are only now becoming more alive to its presence. One may surmise, however, that they are really becoming more common. Ford[29] was able to recover in 1928 113 cases from the literature to which he himself added 12. There were 25 fatal cases in England for the period 1927–30 inclusive, composed in age-groups as follows:—

0– 5 years	.. .. ..	16
6–15 "	.. .. ..	8
16 et seq.	.. .. ..	1

Greenfield, 1929, published four observations, the most interesting of which have been included in the Further Report.[3] Benn[30] has lately added two fatal cases with autopsies.

Table showing Fatal Cases of Infectious Disease with Nervous Complications, recorded in England, 1927–1930 inclusive.

In Germany, Lust[31] described in 1926 4 cases, Bergenfeld 1, Shick 4, Redlich 1, Wohlwill[32] 2 in *1928* with post-mortem examination. In Austria two were observed by Bregman and Ponckz. In France, where Comby had observed two cases in 1921, a case in a normal convalescent after measles has recently been demonstrated by Lechelle, Bertrand, and Fauvert before the Société Médicale des Hôpitaux.[33] At the autopsy it was noticed that the demyelinisation was clearly present, though less accentuated than in others described. In Italy, in 1929, a case was recorded by A. Signa and two by Suvinian (cited by Comby[34]). In the United States, Musser and Hauser[35] recorded eight cases in 1928, collected during the course of an epidemic of 351 cases admitted to the New Orleans Hospital; in 1930, Zimmermann and Yannet gave an account of two cases, and in the following year Ferraro and Scheffer six cases.[36] At Rio de Janeiro, Martinho recorded in 1929 a case of post-measles encephalitis attended by himself (cited by Comby[34]). At Montevideo, Morquio[37] published eight personal observations with one death. The types were varied, acute diffuse encephalitis predominating.

This encephalitis following measles presents the following pathological characteristics:

It appears in children, measles being predominantly an infantile disease.

The attack occurs at varying periods after the onset of the measles. It may begin at the very onset of the measles attack. As a general rule, it follows the appearance of the rash at variable intervals—more usually, however, it appears after the defervescence and the rash has disappeared. It has been observed also during convalescence, or several days, or even weeks, after recovery.

Its incidence is not in conformity with the severity of the cases; light attacks can be accompanied or followed by nervous complications. According to Ford, the encephalitis supervenes in four cases out of 1000.

Its fatality is relatively low. Only about 10 per cent. of the cases at most are fatal; recovery is the rule, although often accompanied by sequelæ.

The symptomatology reproduces the forms and the known types of acute encephalitis; the lesional type conforms to Perdrau's scheme. Proof of this has been plainly demonstrated in recent cases submitted to autopsy and controlled microscopically. For example, the cases of Wohlwill; Greenfield's case, the account of which is given at length in the Further Report; and those of Zimmermann and Yannet, of Ferraro and Scheffer, of Benn, and of Lechelle. Each of these has recorded in much the same language, besides the congestion and the

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Feb. 2nd.—5.30 P.M., ORTHOPÆDICS. (Cases at 4.30 P.M.) Cases: Mr. P. B. Roth: 1. Bone Graft of Radius in a Child. Mr. W. H. Ogilvie: 2. Osteomyelitis of the Pubis. Mr. R. Marnham (for Mr. E. P. Brockman): 3. Case for Diagnosis. Mr. Alan Todd: 4. Non-union of Upper Epiphysis of Femur in a Child. Mr. B. H. Burns: 5. Case for Diagnosis. 8 P.M., PATHOLOGY. Laboratory Meeting at the Pathological Department, Cancer Hospital, S.W. Communication: A. Piney: Blood Changes in Chronic Myeloid Leukæmia after Irradiation. Communications and Demonstrations: A. Piney: Megakaryocytes in the Peripheral Blood. 2. Blood Films from Case of Acute Aleukæmic Lymphadenosis. 3. Adamantinoma of Pituitary. Miss L. M. Hawksley: Adamantinoma of Tibia. W. V. Mayneord and I. Hieger: 5. Fluorescence of Cancer-producing Pitch Fractions and Hydrocarbons. Cancers Produced by 1:2:5:6-dibenzanthracene. J. W. Cook: 5:6-cyclo Pentene-1:2-benzanthracene, a new Cancer-producing hydrocarbon. Harold Burrows: 7. Localisation of Colloidal Dyes. Miss Barry: 8. Experimental Production of Sarcoma. J. M. Woodburn Morison: 9. Radiograms.

WEDNESDAY.—5 P.M., HISTORY OF MEDICINE. Papers: Dr. J. F. Halls Dally: Milestones in the History of Blood Pressure. Dr. Dan McKenzie: Alfred Higginson and the Enema Syringe (illustrated by slides and exhibits). 8.30 P.M., MEDICINE, SURGERY. Special discussion on Diagnosis and Treatment of Abscess of the Lung. Openers: Dr. R. A. Young and Dr. James Maxwell, Medicine; Mr. J. B. Hunter, Dr. Peter Kerley, and Mr. V. E. Negus, Surgery. Other speakers will take part.

THURSDAY.—8 P.M., TROPICAL DISEASES AND PARASITOLOGY. Laboratory meeting at the London School of Hygiene and Tropical Medicine, Keppel-street, London, W.C. Exhibits: Dr. Crowden: 1. The Measurement of Skin Temperature and Radiation by Means of the Moll Thermopile. 2. The Katto High Temperature Thermometer for Use in the Tropics. 3. The Early Detection and Measurement of Deafness . Leeson: 4. Specimens Illus- and Method of Breeding of *xus*, the Vector of American Trypanosomiasis. Dr. Duncan: 5. Fungi Causing Mycetoma. Prof. J. G. Thomson: 6. Animal Experiments on the Effect of Relapsing Fever on Trypanosomiasis (*T. rhodesiense*). Dr. Newham: 7. Specimens from the Museum of the London School of Hygiene and Tropical Medicine. Dr. V. B. Wigglesworth: 8. The Effect of Oil on the Tracheal System of the Mosquito Larva. Dr. Andrew Robertson: 9. *Ditrichomonas ovis* nov. sp. Found in the Gut of a Sheep. Major Edge: 10. Vital Records in Tropical Countries. Dr. N. Hamilton Fairley and Dr. P. Manson-Bahr: 11. Post-mortem Specimen of Multiple Amœbic Abscess Involving Right Half of Liver with Compensatory Hypertrophy of Left Half. Exhibits by the staff of the Department of Helminthology of the School.

FRIDAY.—10 A.M., OTOLOGY. Papers: Mr. W. S. Thacker Neville: Aural Vertigo. Mr. J. S. Fraser: The Pathology of Deaf-mutism (with lantern slides). Dr. Kerr Love: Towards the Prevention of Deaf-mutism—a Review of Forty Years' Progress. Other speakers: Mr. F. W. Watkyn-Thomas, Mr. A. Tweedie, and Mr. F. Brayshaw Gilhespy. 5 P.M., LARYNGOLOGY. (Cases at 4 P.M.) Discussion: Common Colds and Their Sequelæ. Openers: Sir Thomas Horder, Sir StClair Thomson, and Dr. J. Freeman. Cases and Specimens will be shown. Members of the Sections of Disease in Children, Epidemiology and State Medicine, and Medicine are specially invited to attend. 8.30 P.M., ANÆSTHETICS. Paper: Dr. Bernard Hollander: Hypnosis and Anæsthesia.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY, Feb. 1st.—5 P.M., Mr. J. P. Hosford: Some Factors in the Causation of Hydronephrosis. (Hunterian Lecture.)

WEDNESDAY.—5 P.M., Mr. R. T. Payne: Excretion Urography. (Hunterian lecture.)

FRIDAY.—5 P.M., Dr. Remington Hobbs: Puerperal Sepsis, with an account of the Treatment of Puerperal Infection by Glycerin Drainage. (Hunterian lecture.)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Feb. 1st, to SATURDAY, Feb. 6th.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Wed., 4 P.M., Major Meurice Sinclair: Fractures of the Lower Limbs. THURSDAY, Feb. 4th.—9 P.M., Dr. E. ff. Creed: Treatr of Septicæmia.

BEDFORD COLLEGE, Regent's Park, N.W.

WEDNESDAY, Feb. 3rd, and following three Wednesday 5.15 P.M. (in the Physiological Department), Prof. Cowell: Modern Aspects of Nutrition.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Ru square, W.C.

WEDNESDAY, Feb. 3rd.—4 P.M., Dr. D. M. Connan: S Burden of Rheumatic Disease.

SOUTH-WEST LONDON POST-GRADUATE ASSOC TION, St. James' Hospital, Ouseley-road, Balham.

WEDNESDAY, Feb. 3rd.—4 P.M., Mr. J. Swift J Retention.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hosp 49, Leicester-square, W.C.

TUESDAY, Feb. 2nd.—5 P.M., Dr. S. E. Dore: Affec of the Hair and Hair Follicles.

THURSDAY.—5 P.M., Dr. J. A. Drake: Urticaria.

ST. MARY'S HOSPITALS, Manchester.

FRIDAY, Feb. 5th.—4.15 P.M. (at the Whitworth-s West Hospital), Dr. C. P. Lapage: Diseases Abnormalities of the New-born Infant.

FACULTY HALL, St. Vincent-street, Glasgow.

TUESDAY, Feb. 2nd.—4 P.M., Prof. G. B. Fleming: I Feeding.

OTHER INFECTIONS.

e cannot pass without remark the occurrence iro-paralysis in persons who have undergone the ur treatment after being bitten. These disorders e nervous centre, recognised since the beginning tirabic treatment, are rare and do not appear attributable to the rabies vaccine. The lesions ir to be quite similar to those of post-vaccinal halitis, as Basson and Grinker,[48] among others, shown in a fatal encephalopathic rabio-vaccinal

ntion has also been made of cerebral complica- following scarlatina, whooping-cough, diphtheria,

Acute Disseminated Encephalitis.

ie title and description of this condition date the work of Westphal (1872).[49] Further est in it has recently been stimulated by the that all the post-infectious types of encephalitis ld be classed according to their clinical and omical characteristics as special types of acute eminated encephalitis. Acute disseminated phalitis has recently occurred rather in an emic fashion, though it has seemed to arise itaneously and not by any known infectious lition. Consequently there is a special interest considering these cases in relation to theories ost-vaccinal encephalitis.

tedlich,[50] in 1927, published 13 cases, discovered r a period of three years. Those attacked were the greater part adults of over 30 years of age were attacked during the winter months. All them were restored to good health. In the same r, Pette reported 25 similar cases occurring at mburg (cited by Flatau [51]). Flatau records 17 served cases collected at Warsaw and in other ns during the first half of 1928—an epidemic ies of cases with similar symptoms and certain culiarities. Children and young persons were st frequently attacked. The progress of the ease was benign, and there were only two deaths. e clinical characteristics enabled the condition to identified with disseminated encephalitis. stological examination in the only autopsy confirmed e clinical diagnosis. Analogous observations have en published by Brain and Hunter (1929),[52] artin (1928), Spiller (1929), Strauss and Rabiner 930).[53]

McAlpine [54] has recently given a detailed clinical cture and account of the lesions in acute disseminated cephalitis, taking earlier work and deductions into count. He adds a set of four occurrences of sequelæ hich were more or less severe. An apple of discord here thrown among the neurologists; multiple lerosis presents, although rarely, a form characterised y its rapid evolution and a general dissemination f the morbid process (Cournand); and the question as arisen whether this variety should be fused with he other forms of disseminated encephalitis or hould remain in its separate place. McAlpine takes he second view: that acute multiple sclerosis and lisseminated encephalitis, in spite of their similarities, lepend on different viruses. On the other hand, ournand, in his detailed monograph on acute sclerosis.[55] regards *their identity* as proved by the imilarities of the histological lesions with those which have been established for disseminated encephalitis, whether post infectionem or spontaneous. Two personal observations, with sections and reference to Pette's cases, supported this identification of multiple sclerosis and disseminated encephalitis.

Conclusions *of* Part II.

Practically all the authors cited accept, more or less, the doctrine of unity: that one type of virus only is the cause of acute disseminated encephalitis, whether it is deuteropathic (post-vaccinal or post-infectious) or protopathic (spontaneous). This virus, which it has not yet been possible to isolate or handle, must in essence be characterised by its elective affinity for the myelin sheath which undergoes disintegration (demyelinisation). It acts by itself in spontaneous encephalitis, whereas in those following infections it comes into action in the wake of another virus—vaccinia, measles, variola, varicella, &c.—which open the way for it, or enable it to pass from a latent condition to one of infectious activity.

One can no longer refuse the admissibility of this hypothesis, since it is justified by so considerable a dossier of well-established facts and nearly all writers entertain it. Some of them consider the hypotheses of identity as highly probable and others (like Pette, Perdrau, Cournand) definitely assert it. The facts brought forward to support it are certainly striking, although it must be admitted that there are also some discordances to consider. The following may be mentioned:—

(1) While post-vaccinal encephalitis is of recent date, forms of encephalitis post infectionem have long been known, some of them for over a century. The same applies to acute disseminated encephalitis.

(2) The frequency of post-vaccinal encephalitis is much greater, in the countries affected, than is that of post-infectious or disseminated encephalitis. It seems, however, that cases of the latter may be on the increase.

(3) No concomitance in time and place among these different forms of encephalitis has been observed; the post-vaccinal series are not accompanied by cases of disseminated or post-infectious encephalitis, or vice versa. In the Dutch centres, for example, encephalitis was only found among those who had been vaccinated, and not at all among those associated with them.

(4) A relatively constant period of incubation, which is shown in the post-vaccinal cases, is not evident in post-infectious encephalitis. It may be, however, that we have not yet sufficient numerical data on this matter.

(5) The fatality is much higher in post-vaccinal encephalitis than in the others. Disseminated encephalitis is, indeed, conspicuous by its benignity.

(6) Post-infectious and disseminated forms of encephalitis are often followed by sequelæ, whilst in the post-vaccinal these are very much rarer.

(7) The anatomical similarity is not in all respects complete. In addition to the perivascular infiltration and the demyelinisation, one meets with different somatic lesions, such as signs of intense inflammation and hæmorrhages, particularly in the case of the post-infectious encephalitis.

It may be that some of these differences will be effaced as observations continue and increase. The materials are scanty owing to the relative rarity of all these kinds of encephalitis; cases still go undetected, and very few are observed throughout their course and completed by autopsies.

Direct proof of the existence of a single virus for all these forms of encephalitis—one which would remove all doubts—has still to be furnished and may be long in coming. The conception of unity rests on the identity of the lesions, and is based on the myelin proof. On the other side, it may on principle be urged that the same histological process can be engendered by diverse infections, by diseases which are very different in respect of their ætiology. The histological proof in itself is hardly sufficient to carry full conviction. But if in place of unity one assumes *plurality of the viruses*—that is to say, that each encephalitis, post-vaccinal, morbillar, varicellar, variolous, &c., is due to its own virus which, as the result of its neurotropism, has succeeded in attacking the nervous centres—one has then to ask if it is reasonable to suppose that so many different viruses would attack the nerve tissues in the same manner, with the same localisation, the same selectiveness, and the same microscopic characteristics.

The assumption of a single encephalitogenic virus which is associated with the different viruses of these diseases followed by nervous complications seems to be in more logical accord with the facts known up to now. It is, however, simply a *provisional synthesis* resting at the mercy of scientific progress, which, by confirmation or invalidation, will give us better and surer conceptions. These we must be ready to entertain without tying ourselves to preconceived opinions.

At least the main lines of the problem have now become clear and fruitful results have been obtained hæmorrhage, a perivascular infiltration, though often very slight, and a typical demyelinisation.

SMALL-POX.

The series of encephalitis cases following small-pox which have been recently recorded are few in number. Nevertheless, knowledge of nervous sequelæ of small-pox dates back for two centuries. Reference is made to them, according to Greenfield, in the writings of Clifton (1724) and Freind (1730) and they have also been observed as following variola inoculation (Dunsdale, 1757) (communication by Dr. Hutchinson). This detail suggests that small-pox inoculation could cause cerebral infections in the same way as cow-pox; nevertheless, even at this distant epoch, if encephalitis complications had been prevalent epidemically among small-pox patients as is the case to-day among vaccinated persons, the circumstances should have been known and recorded. More recent writers recall this occurrence of nervous complication; and among them MacCombie (1905) states that in small-pox the nervous system is more often involved than is the case in other eruptive fevers (cited by Troup and Hurst [33]). Rolleston only found 25 examples out of 10,000 small-pox cases in London in the epidemic of 1901–02.

During the five years 1925–29, 23 cases of death from small-pox accompanied by various nervous complications have been registered in England, and some of these were definitely diagnosed as encephalitis. In two of them the encephalitis was duly confirmed; McIntosh and Scarff described a case of encephalitis following small-pox in 1928, and another, in a man of 63 years, was given by Troup and Hurst.[38] A third case is noted in the Further Report. In all these there was similarity in the clinical facies and identity in the histological findings—a cellular infiltration around the vessels and zones of disappearance of the myelin sheath.

A curious case was cited in the Further Report. A boy vaccinated six days previously fell ill with small-pox; two days after the rash cerebral symptoms appeared but he eventually recovered. It is not clear whether the encephalitis should here be put to the account of vaccinia or variola.

The Ministry of Health has unpublished notes concerning four cases, one of which is interesting, not only because of the age of the patient, 63 years, but because of the precocity of the nervous symptoms which preceded the small-pox eruption by two days. It should be noted that encephalitis can occur in variola minor as well as in variola major; as in the case of measles, it does not depend on the severity of the disease. Nervous complications in the case mentioned in the Further Report arose four days after the onset of small-pox; in the Troup and Hurst case the period was 12 days. In that particular case small-pox ran a normal course in 15 other persons who had been infected from the same source.

VARICELLA.

Encephalitis after varicella has been described by various observers, though cases are not common. In 1924–25 Toni and Galli drew attention to this complication of varicella. D.W. Winnicott and N. Gibbs (1926) and Glanzmann (1927) [39] brought forward some new cases, and the latter considered their pathogenesis. Wilson and Ford [40] in 1927 recorded three histories all ending in complete recovery.

Bertoye and Garcin in 1929, Robert Rendu in 1930, and P. Gauthier in 1931, recorded similar cases (cited by Comby [34]).

Rake [41] described a very clear case in connexion with which he makes a survey of known literature. Tramer [42] also records a case with encephalitic symptoms. Eight cases have been recorded by the English Ministry of Health, all in infants below 5 years of age. Bouman has recently mentioned a case after varicella which he considered quite characteristic, followed by recovery, in a child of 4 years of age who had never been vaccinated (communication of Dr. Jitta). Babonneix [43] attrib to encephalitis the convulsive attacks of Jacks type which occurred in two infants with varic He also mentions another case, also after varic with complication of symptoms. The period o incubation is said to vary from five days from the appearance of the rash to 15 days and even mo The prognosis is quite favourable. There have b no autopsies, so that the diagnosis of typ encephalitis can only be assumed.

MUMPS.

It has long been known that epidemic parotitis can be accompanied by meningo-encephalitic phenomena Acker, in 1913, was able to collect 30 fatal cases, and several came to light during the war. Bedfield (1927) [44] described a case, and refers to prev literature on the subject. K. Holtz has (1931) giv an account of another case with meningeal sympto occurring two days after the swelling of the rig parotid, and has collected 16 fatal cases since 191 A benign form would appear to be usual in children the condition seems to be more severe among adults

The cerebral manifestations occur after the swelling of the parotid, though it seems that sometimes they may precede the appearance of the parotitis. No deaths and no autopsies.

GERMAN MEASLES.

Pierret and Le Marc'Hadour [45] in July, 1931 described to the Société de Médecine du Nord a case of meningo-encephalitis occurring during mild measles with death after 36 hours. A similar case had been described by Brock [46] in 1929. Debre Turquéty, and Broca [47] also dealt with this type c encephalitis in 1930 on the basis of two observations In both, though the affection was well-marked recovery was rapid. Babonneix [43] described a ca following rubeola accompanied by diffuse lesions the nervous system and terminating fatally after protracted development.

No autopsies have been recorded which wou determine the precise nature of the affection.

INFLUENZA.

In influenza we have a virus endowed with selective affinity for the nerve centres. Po influenzal encephalitis occurs more or less frequen during the course of the great pandemics of influen and also during the ordinary seasonal recrudescenc So well was this realised that at the time t encephalitis lethargica made its appearance, it w considered natural to regard it as dependent on t universal influenza epidemic of 1918. The Briti statistics record 99 fatal cases during the peri 1927–30, the great majority being adults.

Much has been written on post-influenzal encepha myelitis and its lesions, but what interests us for t moment is to know whether from recent autops it has been possible to discover histological lesio similar to those of post-vaccinal encephalitis. cases in adults, studied by Greenfield, were publish in the Further Report; one was fatal five da and the other seven weeks, after the appearance the encephalitis. The post-mortem examinati revealed the same lesional picture as in encephali following other infections—cellular infiltration rou the vessels with concomitant demyelinisatio McAlpine was of opinion that the second case w one of idiopathic encephalitis rather than due influenza. One might, however, consider it mo probable that a light and simple infection, su as an angina, a cold, or bronchitis, can origina the encephalomyelitis, whether influenzal or n (G. Buchanan, Report of the Small-pox Committe 1930).[3]

Influenzal encephalitis in the light of the earli reports appears to be of a complex and variab nature. The vascular lesions—congestion ar hæmorrhage—are very pronounced, and the inflam mation may even at times become purulent.

raft of goldsmiths and other workers must use fire. How they shall deal therewith and drive he poisons.

e skilful, subtle and noble craft of Goldsmithery of perial City of Augsburg.

willing devoted service be ready for you all. As h Ellenbog, Doctor of Physick, of Feldkirch, now an to the Dean and Chapter of Augsburg Cathedral, bserved the great, severe and remarkable harm o this skilful craft cometh through the fumes and s of the things wherewith the said craft hath to so I could not withhold or refrain from giving advice service and help of the craftsmen, that they come such grievous harm or disease through these fumes. pray you, masters and men, that ye take in all good nd friendship this my little advice, written with own hand, then the readier will I be with friendly s to you each and all who command and work. at Augsburg the 6th day of October, 1473.

he fire of coals.—In your subtle craft ye use coals for e. The smoke or vapour of the same is poisonous articularly if the coals be somewhat damp, for this r burdeneth the head and also the chest, especially if e near it for long, and when one tarrieth there too the sight waxeth dim, so that it seemeth as if there be and blue and such like before his eyes, or flies in the This vapour also maketh heavy, unnatural sleep and nes heavy limbs, and if one be therein for long he neth palsied. Therefore burn not much damp coal, kindle in the open air. In winter time when ye have fire in the workshop, shut not the windows and guard selves from this vapour so far as ye may, is my advice. writings shew that it is quite poisonous and deadly to nd sleep for long in a closed room with this coal-vapour. any masters in physick prove this, for brevity's sake it eth not be pointed out. If ye craftsmen will use coal first kindle and blow them up in the open air, then white incense therein or sprinkle a little wine thereon. ill the poison and harm of this vapour be lessened.

the vapour of quicksilver, lead and other metals where- goldsmiths do use to work.

he writings of physick hold that the vapour of every g retaineth the nature, complexion and power of the y whence it issueth. Wherefore are the apothecaries t to make distilled waters that are of a hot nature when take hot herbs, and from cold herbs they distil cold ers. Wherefore is it also that the smoke or vapour of a metal retaineth the complexion, nature and power he metal wherefrom it issueth. And often the vapour moke is stronger, mightier and sharper than his mineral, al or body, as one manifestly seeth if one sublimate a fortis, also if one distil brandy, for the vapour is much nger than the sal ammoniac alone, etc., or also the wine erefrom the brandy is made. Wherefore men call and ne the vapour spirits, that is ghosts, for through their rpness, strength and subtlety, they always penetrate l work more strongly than the body wherefrom they drawn. Now it is apparent in the writings of nature that icksilver is right cold and wet in his complexion and also ion, also that lead is cold and wet, likewise that silver of a cold nature, likewise litharge and antimony are cold. herefore I say that the smoke and vapour of the said etals chilleth greatly the man who hath to work therewith. herefore when ye masters and men work silver with lead, gild, ye shall guard yourselves as far as ye may from the pour and smoke, for it is poisonous to you, and it is my lvice that ye do it in the open air with all diligence, and ot in a closed room. Also ye shall not bend too much er this vapour but turn away therefrom and bind up the outh. This vapour of quicksilver, silver and lead is a ld poison, for it maketh heaviness and tightness of the est, burdeneth the limbs and ofttimes lameth them as ten one seeth in foundries where men do work with large asses and the vital inward members become burdened herefrom.

How One Shall Lessen and even Turn Aside the Harm of these Vapours.

Dear masters and men, when ye refine or gild, have musk y you, and ye shall smell of this much and often, for the apour of the musk quelleth and suppresseth by his warmth he coldness of the smoke from silver, lead and quicksilver. Also the musk, by the property that it hath of strengthening he vital members of the heart and brain, wardeth off and ssuageth the harm from the vapour of lead and quicksilver, therefore the same vapour cannot harm you so. Likewise what time ye goldsmiths be in the aforesaid fumes, keep *in* your mouths one of the following pieces, which ye will, and chew it, so by the strength of these pieces will be corrected and lessened the poisoning of the vapour that ye draw in with the air for your breath. Thus the said vapour cannot so harm you as if ye held not the pieces or their like in your mouths. And these are the pieces: juniper berries, rue, dittany, that is a pure white root, tormentil, elecampane.* Many other pieces are commended by the physicians against these poisonous vapours, but these aforesaid seven pieces are good for you, also common enough that ye and everyone can get them at small cost. Some teachers of physick highly commend the emerald, which one shall also hold in the mouth, for it withstandeth the poisoning of this vapour. Also, dear craftsmen, if one of you in gilding or refining hath inhaled much vapour, so that he feeleth distressed or feareth harm, he shall on the morrow, fasting, sweat in bed and then take a good old theriac such as a large hazelnut with rue-water or speedwell-water or wine, thus will the poisoning be driven out of him, which hath entered him in refining or gilding. The doctors also recommend that ye shall after refining or gilding drink wormwood wine, for by the warmth and heat of the wormwood the chilling of the said vapours will be suppressed. Moreover wormwood hath the property that it withstandeth the poisoning. And he who hath no wormwood wine in his cellar may in a day or seven hours make it by dropping wormwood into wine. If however one cannot sweat in bed, he shall go on an empty stomach to the bathroom and take the theriac as before directed.

Against the vapours of aqua fortis which are warm, hot and right sharp, and against the vapours of litharge and antimony, which are of a cold nature, ye shall guard yourselves specially well as is described above for lead and quicksilver. Also some teachers say one shall eat garlic before and after against suchlike poisonous vapours.

Against the vapours of verdigris, saltpeter, and sal ammoniac guard yourselves right well because when ye fire pale gold, then these vapours are very hot, sharp and poisonous. To correct and lessen their poisoning thou shalt drink half a dram of bole mixed with wine and rosewater. Herewith God keep us all sound. Amen.

HYPODERMIC NEEDLES OF BRITISH MANUFACTURE.

WE have received from British Surgical Industries, Ltd., 14, Regent-street, London, samples of their hypodermic needles in stainless steel with gold finished mounts. These are also made in the finest quality of Sheffield steel with silver finished mounts. The specification of the needles supplied to us is size 15, 28 mm., bore ·37. The aim of the firm is to supply the profession with dependable articles at lower prices than are now charged for those of foreign origin.

A PHOTOGRAPHIC RECORD OF RADIUM CASES.

THE radium workers at the Middlesex Hospital have conceived the interesting idea of publishing a photographic record of some of their successes and failures.[1] As they point out in their preface, radiotherapy is in its infancy, and a record of the results obtained at this stage may prove of great value in the future. The bulk of the book consists of very beautiful untouched photographs of superficial malignant growths before and after the application of radium. The cases are classified as carcinomata (squamous-celled, basal-celled, spheroidal-celled), sarcomata, and miscellaneous (lupus vulgaris, lupus carcinoma, and odontoma). Each photograph has a by pursuing them. It is greatly to be hoped that they will be pursued; that, on the one hand, the investigators will persevere in the study of experimental encephalitis and, on the other hand, that the course of post-infectious and disseminated encephalites will be closely followed. All these studies should be vigilantly watched. They already come under official supervision in England, Holland, Germany, Sweden, and elsewhere. Medical practitioners should notify any cases recorded by them in order to obtain an examination by an expert neurologist, laboratory determinations, and, in fatal cases, a post-mortem examination by an expert in the pathology of the nervous system. The Ministry of Health in England has recently addressed to practitioners a request that they will communicate without delay all cases with acute infection of the central nervous system which have occurred within four weeks after vaccination, or in which the symptoms have immediately followed an acute infectious disease. All such collections of carefully made observations will bring us nearer to wider and exacter knowledge.

SALE AND PURCHASE OF PRACTICES.

WE have received from Mr. Percival Turner a little volume which is a partial reprint of the "Guide to the Medical and Dental Professions" which he wrote some years ago and which is now out of print. These "Hints," as the author terms his excerpts, relate particularly to the sale and purchase of medical and dental practices and partnerships, and include much information given in the previous publication, when it remains relevant to existing circumstances. We may draw attention to the fourth chapter which sets out the circumstances for the employment of assistants and locum-tenents, for every practitioner knows there are many difficult positions that may arise in these relations, such as the death or bankruptcy of the principal or the employee, the failure of one or other party to keep the terms of the contract, the misunderstanding of agreements for special services, travelling expenses, and so on. Mr. Turner gives wise counsel on these and analogous points out of his long experience.

PROBLEMS OF WATER POLLUTION.

FOUR years ago the Water Pollution Research Board of the Department of Scientific and Industrial Research began to issue a monthly series of abstracts on sewage, water-supply, and pollution. In the Board's latest report * Sir Robert Robertson remarks that these are stimulating industrial concerns and individuals to carry out experimental work on their own problems. The first number of the new volume of 123 abstracts † contains a note on the hygienic control of public baths in Greater Berlin, the water of which is required to be clear, to be free from the colon bacillus in 100 c.cm., and to contain not more than 200 bacteria per c.cm., the content of free chlorine being not less than 0·1 and not more than 0·5 parts per 1,000,000. The replacement of chlorination by treatment with copper or silver (whether or not in the form of catadyn is not stated) was tried in some cases, and copper alone was found to reduce troubles from slime. Swimming-bath conjunctivitis has not appeared in these baths for some years. In another note it appears that the water-supply of Los Angeles is so critical that the reclamation of sewage has been investigated. We are familiar with the necessity of using a circulating system for the water-supply of many modern country bungalows, but the possibility of converting sewage into a normal supply of drinking water goes far beyond this. It seems to be proposed to maintain the ground-water level in this way.

ULRICH ELLENBOG.

REFERENCE was made in THE LANCET (1931, ii 809 and 997) to a fifteenth century treatise o industrial hygiene mentioned by Dr. L. Caroz in his historical review of occupational disease It may be of interest to note that this was reprint in facsimile in 1927 [2] from the only known copy the first issue in Munich University Library. copy of this reprint is in the library of the Lond School of Hygiene and Tropical Medicine. Preced the facsimile is an account, by Friedrich Zoe based on his longer article,[3] of the life and work Ulrich Ellenbog (not Ellembog, as Dr. Carozzi sp it). The name is probably derived from Ellenbo in Vorarlberg, Austria, about 30 miles east of Ulric birthplace, Feldkirch. He was educated at universities of Vienna, Heidelberg, and Pavia, gradu ing as Doctor of Medicine at the last named in 1 He then returned to his home town of Feldki Later he occupied an official position as physi to the Cathedral in Augsburg, where his trea was written. He was a devoutly religious and paid particular attention to the religious educa of his 11 children, four of whom later entered service of the Church. He died in 1499. Thre his works were printed, four are known onl manuscript, while five others are lost. A account of the present pamphlet from the me point of view has been provided by Franz Koe who claims for it the distinction of being the work on industrial hygiene in the literature of world. A typographical study follows from the of the editor, who concludes that although the was written in 1473 it was not printed till by Melchior Ramminger in Augsburg.

Since the reprint itself is not easily accessible, Ellenbog's fifteenth century Swabian is not easy reading as modern High German, Mr. Barnard, Librarian of the London School of Hy and Tropical Medicine, has made a translation o text; this occupies only eight small pages in original, and the translation is complete.

THE TREATISE.

On the poisonous evil vapours and fumes of m such as silver, quicksilver, lead, and others tha

HE ÆTIOLOGY OF CARCINOMA.

J. M. SHAW, M.C., M.D., F.R.C.S., F.R.S. EDIN.,
ANT SURGEON TO THE ROYAL INFIRMARY, EDINBURGH:
LECTURER IN SURGERY AND ASSISTANT TO THE
PROFESSOR OF SURGERY IN THE
UNIVERSITY OF EDINBURGH.

(Concluded from p. 224.)

Chronic Irritation.

HE phrase "chronic irritation" is given so much nence that it must be assumed to convey a ise scientific meaning to many minds, and it has distinction of being the oldest hypothesis of the e of cancer. Perchance some of you have felt, . have, that the connotation of the words is so ce that they are not helpful in dispelling the ts which obscure our vision. "Tar, jagged teeth, ses and that sort of thing," as they were once mplified to me, will not carry us sufficiently far ng the road and may even prove a stumbling-block. he connotation of the term is felt to be vague, it oves us to remember the precept from Logic that, scientific use, the connotation of a term is determined by and is the same as its definition, and to carry the instruction that the definition is determined examining the things to be denoted.

Leitch has pointed out that few of the substances ich we might call tissue irritants are capable of ucing tumour growth, just as out of the myriads of ds of bacteria there are relatively few which are initely pathogenic.[15] Greenfield states: "If we gard the processes of irritation as a whole, we find all of them a series of reactions combined for the mmon object of removing or antagonising the itant and of preventing and repairing damage."[19] The persistent manifestation of the process of pair" has been described as the effect of the chronic itant, and the general conception is the "response y proliferation and increased cellular activity to the resence of something which is foreign to the cells of he body."[20]

It should be stated here that the conversion of a roup of cells of normal type into those with the ppearance and properties of carcinomatous cells is not necessarily followed by the establishment of a arcinoma. Two further stages are necessary. The ell must irrupt from its natural locus as an epithelial unit and, further, it must be capable of surviving this critical transfer and multiplying in the tissues of the host. Cheatle has ably emphasised this point, and frankly states his belief that the altered cells lying within the ducts of the breast are, in fact, cancer cells in form and metabolism, although they have not yet secured ingress into the connective tissues of the host.[21] He and Fraser[22] have succeeded in obtaining microscopical demonstration of this stage in the life-history of the cell. The problem then comprises these three stages of conversion, transfer, and multiplication, of which conversion is the most important in relation to ætiology.

Action of the Irritant.

In attempting to impart a precise meaning to the phrase "chronic irritant" I would like, in the first place, to draw your attention to the action of an irritant upon an epithelial surface. This has been described in masterly *fashion by Lewis in his work* on the "Blood-vessels of Human Skin and their Responses."[23] A triple response is shown on the application of a stimulus, mechanical or chemical, to the skin surface, the stages being first a local vaso-dilatation, second the "flare" or spreading flush, and third, a local œdema. By this means the chemical irritant with the histamine substance which it has evoked are diluted and neutralised and finally carried away from the site of irritation in the blood and lymph channels. Many examples of this rapid reaction could be cited. The application of formic acid illustrates it well.

Instead of a single sharp application of the chemical irritant, I would ask you to visualise the effect of such a stimulus if very much prolonged. In such circumstances a strong irritant would, of course, produce necrosis. With a weak irritant, however, a highly important series of changes occur which have a definite bearing on the question of carcinogenesis. For the recognition of these changes we are indebted to Kreyberg, of Oslo, whose brilliant work should command the widest attention.[24] Using tars, 5 per cent. mustard oil and the prolonged application of heat, Kreyberg has shown that there is a limit to the capacity of the minute blood-vessels to return to normal after the unduly long stimulus of an irritant. After a period averaging about five weeks in mice experiments an "ectasia" of the vessels is produced by the throwing out of gear of the local vaso-motor reflex. This dilatation remains permanent and is followed by a capillary thrombosis and an associated local connective tissue fibrosis. Respiration of the cells is interfered with by this deprivation of capillary oxygen. On account, however, of the slowness of the process, the successive generations of affected cells have time to develop that reserve method of obtaining energy which characterises all malignant tumours, namely glycolysis, in which the carbohydrates are split with the production of lactic acid. Warburg says:

> "Interference with the respiration in growing cells is, from the standpoint of the physiology of metabolism, the cause of tumours. If the respiration of a growing cell is disturbed, as a rule the cell dies. If it does not die, a tumour results."[25]

I have ventured to place the views of Kreyberg and Warburg in sequence in this way because they appear to justify this important inter-relation. It will be apparent that the vascular reactivity will be more readily deranged by the prolonged application of an irritant if, at the outset, the local blood-supply is deficient, as in many scars, or if the blood-vessels are diseased, as in tertiary syphilis. Lumière has emphasised the susceptibility of scars to the action of irritants, and the high proportion of syphilitics as subjects of buccal and lingual carcinoma is well recognised. The carcinogenic irritants are undoubtedly numerous, and we will agree with C. H. Mayo when he says: "There is no one cause for cancer; all merely contribute through their chemistry to end-results upon cell growth."[26] Kennaway, Hieger, H. M. and C. C. Twort have proceeded far in isolating some of the irritants among such of the mineral, animal, and vegetable oil groups as are carcinogenetic.

Medium of Application of the Irritant.

Now arises the fundamentally important question, "by what means is the necessary chronicity or constancy of application imparted to the irritants so that their service to the cells is continuous and prolonged?" I would answer this question by the suggestion that the responsible factor is the physical brief clinical note attached to it. There is a short history of the technique employed at the Middlesex since 1912, and each section of photographs is introduced by two or three pages of letterpress on the technique employed and the results obtained.

PRACTITIONERS' REGISTER OF DANGEROUS DRUGS.

We are informed that there is still some misapprehension about the requirements of the Dangerous Drugs (Consolidation) Regulations concerning the keeping of registers by medical practitioners who do *not* dispense or supply drugs to their patients. Every such medical practitioner who obtains the drugs for whatever purpose is, by No. 11 (1) (A) of the Regulations, required to keep a register in the form set out in the second schedule to the Regulations and enter therein true particulars with regard to every quantity of any of the drugs obtained by him at the time he obtains them.

STAINING SMEARS FOR THE MICROSCOPE.

There are many small pedantic practices which take up much time and might well be replaced by something simpler. Where for example, microscopical control is of decisive importance in diagnosis the usual plan is to take a smear and lay it by for further treatment and investigation. To simplify these operations Dr. Felice Marta,[1] of Milan, uses an ordinary copying pencil. The smear being obtained, the tip of the pencil conveys a drop of water on to the slide beside it. In a few seconds the drop is adequately coloured by the pencil, and it is then allowed to glide over the smear which rapidly absorbs the stain. When dried, the smear shows uniform staining with clear definition of cells and nuclei, transparent in the free spaces, and especially an intense colouration of the microbic elements which Dr. Marta says is more distinct than that obtained by the usual colouring agents. The make of pencil is of no importance, but its colour is; the best results are obtained by blue, violet, or green, the colour being due to acidity or alkalinity of the aniline pastel, while red and yellow show admixture with earthy substances.

INDEX TO "THE LANCET," VOL. II., 1931.

The Index and Title-page to Vol. II., 1931, which was completed with the issue of Dec. 26th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of The Lancet, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

Appointments

Thomas, L. Glynne, L.R.C.P. Lond., M.R.C.S., has been appointed Resident Asst. M.O., Infectious Diseases Hospital, Birkenhead.

Births, Marriages, and Deat

BIRTHS.

Cory.—On Jan. 20th, at Bury St. Edmunds, the wife o W. E. Cory, of a son.

Dewhurst.—On Jan. 21st, at Shawfield, Havant, the Dr. M. S. Dewhurst, of a son.

Platt.—On Jan. 23rd, the wife of Harry Platt, M.S., F of Newbury, Victoria Park, Manchester, and Ronda Prestbury, Cheshire, of a daughter.

MARRIAGES.

Taylor—Pratt.—On Jan. 14th, at Marylebone Registe Alexander Giles Cameron Taylor, M.R.C.S., L.R. Bellefields, Englefield Green, Surrey, to Norah, only d of the late A. H. Pratt, and of Mrs. Pratt, of Epsom

DEATHS.

Craven.—On Jan. 16th, suddenly, at a nursing home in Walter Craven, M.R.C.S., L.R.C.P., late of Umtali, S Rhodesia.

Hendley.—On Jan. 21st, suddenly at The Thatched Caxton, Cambridge, Major-General Harold Hendle (I.M.S., retired), in his 71st year.

Henshaw.—On Jan. 20th, at Shawfield-park, Bromle Harry Williams Henshaw, M.R.C.S., L.R.C.P., aged 63.

Shute.—On Jan. 20th, 1932, suddenly, at Granby-place fleet, Geo. Sidney Shute, M.D., aged 69 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of N Births, Marriages, and Deaths.

the persistent retention of epithelial oral debris. is the evidence of disorder in the lower alimen- ract, the mildly irritant elements accumulate in ucinous film.

example means very little but will serve to explain aning. Recently a sailor of 29 years of age presented f at hospital with an epithelioma of the hard palate year's duration. He had worn dentures for five and on being asked the routine question as to their g pain he replied, "No. That is the trouble. They o comfortable that I wore them for several days and , at times, without cleaning them."

uld suggest that this adhesive, stale, slimy sub- e is worthy of consideration as a responsible r, as the retained debris of the tonsillar crypts pharyngeal recesses may also have an action upon nucosa with which it is in long contact.

the *urinary bladder*, I would refer to the only p in which an unduly high incidence is alleged— ely, the aniline dye workers. In such cases the inoma is, apparently, always preceded by a nic hæmorrhagic cystitis. The exemption of the ley in these workers may be thus explicable.

n the *lung* the association with old infected cavita- is recognised, and in the best known occupational dence—i.e., among cobalt workers—a chronic foul nchitis is stated to be very common as a precursor he carcinomatous change.

VARIOUS ADJUVANTS TO THE APPLICATION.

Burns of all types (thermal, X rays, khangri, kairo,) may be followed by carcinoma. It is, however, imperfectly healed burn or the one associated with hronic fissure or ulcer. with chronic dermatitis or atosis, which produces the condition. In such es the stagnant secretion, its irritant action inten- ied by infection, may operate for several years. e partially destroyed skin gland may continue to rete in the depth of certain keloidal burn scars, d in these a basal cell carcinoma supervenes. The ain lesson of a masterly analysis of the development cancer in burn scars by Treves and Pack from the emorial Hospital in New York is the fact that severe rn scars are so prone to break down from tension, chæmia. and trauma. and that carcinoma arises at a te stage in the persistently broken surface.[36]

Arsenic has been described as a cause of cancer. he external application of this substance has not roved dangerous. When taken medicinally over ng periods it may produce a very chronic dermatitis r adhesive hyperkeratosis. No human case is on ecord in which the carcinoma has not been preceded y such a change. While the arsenic is thus respon- ible for the chronic skin changes, it is probable that he prolonged action of the unshed skin debris is the esponsible intermediary with the same irritative action as is shown in a chronic intertrigo. For a very complete description of the late effects of the prolonged exhibition of arsenic I recommend the contribution of Pye-Smith, Nutt, and Beattie.[37]

Lupus is an accepted precursor of cancer, but again the carcinoma supervenes in those areas in which fissuring occurs. such as the angle of the nostril or around the mouth or in an isolated portion in which the disease still smoulders in raised yellowish patches which, on scraping, yield a greasy mass of cell debris and stale exudate.

In the experience of an expert like R. L. Sutton a *seborrhœic keratosis* of long standing, often the result of actinic action, is the commonest precursor of epithelioma.[38]

Roffo has produced a carcinoma on the ear of a rabbit by the application of an admixture of *tobacco* oil.[39] I have never been able to advance beyond the stage of hyperplasia in many mice experiments with this substance. The difficulty in tobacco oil experimentation is that it tends to solidify at normal temperature, like a resin. after a short time. A certain degree of oily viscosity is an essential in the medium. I would make the suggestion that this viscosity may well be maintained in the stem of a hot porous clay pipe.

The researches of Fibiger have received wide and well-merited attention. No suggestion has been made, except by Sambon, that the presence of a gross *parasite* in the tissues is in itself a cause of cancer. A large variety of parasites dwell harmlessly in this way. I would commend the suggestion of Leitch that the start of the malignant proliferation is probably due to the prolonged toxic action of some excretion of spiroptera.[40]

CARCINOGENESIS IN THE ALIMENTARY TRACT.

The alimentary tract forms, in my opinion, the outstanding example and verification of the chemical nature of the carcinogenic irritants and also, I submit, of the importance of the medium from which they act. The extreme disparity in incidence between the small intestine on the one hand and that of the stomach and colon on the other seems to be explicable only on a chemico-physical basis. In the stomach and colon the action of the irritants is intensified in an acid medium, and the tenacious mucus in these sites renders their application constant. The fatty acids are formed in great excess in the large bowel by the action of bacteria upon the carbohydrates. In conditions of chronic gastritis and of colonic stasis the disintegration and interaction products of the fatty acids acquire a toxic and irritant quality which is absent under the healthy conditions of rapid passage. Per contra, in the small intestine these acids are saponified and rendered soluble as one of the main processes of digestion and the mucus medium is emulsified and passed on quickly.

EXTRAVASATION OF BLOOD.

The action of the insoluble elements of extravasated blood, chiefly fibrin. and the lactic acid which is produced when the blood leaves its normal channels are of importance, especially in the ætiology of sarcoma. Extravasated blood would also. however, appear to be the responsible potent substance in the undoubted acceleration of growth which occurs in a carcinoma when contused or incised or incompletely removed by surgical means. By hæmorrhage into a simple tumour, as by a myxomatous degeneration, a change in the character of the neoplasm may be induced. The rapid increase in the lactic acid content has been demonstrated in blood after withdrawal from the vessels and allowing it to stand for varying periods.[41] In a series of observations upon hæmatomata, formed in rabbits by the subcutaneous division of the femoral artery, a comparison was made between the lactic acid therein and that of the blood in circulation. Dr. C. P. Stewart kindly analysed the samples for me and found a definite and progressive increase in the lactic acid content of the extravasated blood at periods of 4, 8, and 24 hours after severance of the artery. A very oblique wound prevented any escape of the blood to the skin surface in this little operation. Ewing writes:—

> "The organisation of considerable masses of blood provides conditions favourable for very free growth of atypical cells. Some organising blood clots after fracture I have found quite difficult to separate from sarcoma. Formation of progressive traumatic angiomas which gradually extend beneath the periosteum, often enclosed by a shell

nature of the medium in which the irritant substances are suspended or dissolved. This medium must be insoluble in the tissue fluids, must be viscous in consistency, and must evaporate with extreme slowness. Gas-works tar will serve as an illustration of the embodiment of a chemical irritant in a medium which secures its prolonged action. To such combinations we will apply, for convenience, the term "potent substances."

Two examples will serve to demonstrate the dual nature of the potent substances with their irritant factor and constancy factor.

> Leitch recognised the irritant nature of pitch dust and its relation to the skin cancers of briquette makers. To secure its prolonged application, he dissolved it in human sebaceous oil, producing cancer in mice in less than three months by this means.[27]
>
> Twort believed that three irritants—chrysene, truxene, and benzerythene—were, in conjunction, capable of inducing cancer experimentally. To obtain their action, he suspended them in liquid paraffin, producing thus a carcinoma.[28]

Throughout the whole field of experimental carcinogenesis one is impressed by the universal use of the tars and oils as potent substances. Ethereal solutions of such substances act, of course, by the production of a fine film of the oil after the rapid evaporation of the ether. I know of only one recorded exception to this rule, where Leitch and Kennaway applied a very weak solution of potassium arsenite in water and alcohol to a large number of mice. In one mouse a carcinoma appeared. They repeated the experiment on several further series of mice, but failed to produce another positive result.[29] I have tried to obtain a cancer by this means in three series of mice totalling 150 animals without success. Spontaneous epithelioma does occur in mice, although rarely. In the incrimination of arsenic in the fate of this particular mouse, perhaps it would be permissible to state that the question is still sub judice.

In the cancers of occupational origin, one is similarly impressed by the effect of the tars and mineral oils in contrast to the absence of occupational cancerous skin conditions in the thousands of workers who are exposed to the action of undoubted chemical irritants applied in aqueous solution in which they are capable of rapid neutralisation and dilution. Henry, one of H.M. Inspectors of Factories, has given a valuable analysis of the occupational cancers, and his findings bear out the above statement. He refers to the fact that such an irritant as chrome has never yet been known to produce cancer.[30]

Medium of Application under Natural Conditions.

Can we proceed from the experimental and occupational categories to apply these views of a physico-chemical causation to the other, more common, varieties of cancer? I would suggest that this can reasonably be done, the place of the hydro-carbons, with their contained irritants, being taken by a variety of insoluble oily or greasy substances, such as the stale retained secretions, purulent exudates, the mucins under certain conditions, and the insoluble elements of old extravasations of blood. The toxic, irritant moiety in such insoluble media is formed, predominantly, by breakdown products of the fatty acids which accumulate in them and tend by staleness towards rancidity. I need not enter into a description of the large and important group of the fatty acids, except to remind you that many of them are insoluble in water and that they become saponified with the formation of soluble soaps in the presence of alkalis. The effect of these acids, especially lactic acid, is at present the subject of wide attention in relation to the cancer process and its genesis. Cramer refers the marked toxicity of lactic acid and to its peculiar digestive action, even in weak solutions, which causes a slow tissue necrosis.[31] Bierich and Rosenbohm state that, after the examination of a large number acids, bases, and alkalis, the only reagent which produced the same series of changes as are manifested in cancer is lactic acid.[32] Twort has produced papilloma with oleic acid, another of the group. He states that a well-marked hyperplasia of the skin of the animal treated is consistently present, and he awaits the advent of malignant tumours with confidence.[33] Bierich describes the solvent action of lactic acid upon collagenous tissues and states precisely that "lactic acid is the direct cause of the malignant invasion of normal tissues by tumour cells."[34]

Substances which are innocuous in pure form and in healthy organs tend to become toxic and irritant when decomposing under conditions of morbid stasis. The breast, the sebaceous glands, the prostate, and the subpreputial sulcus come readily to mind as areas in which these stale secretions may be operative. I shall quote from an excellent recent paper by Charteris[35]

> "The suggestion of mammary stasis has been strengthened by the finding of cysts, the contents of some being under considerable tension, and, moreover, it is well recognised that the material filling these dilated structures is usually quite abnormal in appearance, being often of a soft cheesy or thick creamy nature. Adair and Bagg found from a detailed clinical study of 200 consecutive cases of breast cancer, that only 8·5 per cent. of the women so affected had an apparently normal mammary history. In the remainder some abnormality was found from clinical data alone which appeared to justify the assumption tha mammary drainage had been defective. They believe tha the products of stagnation, decomposing and chemicall altered milk, mucus, &c., stimulate an excessive growth the epithelium lining the ducts and acini, and that, whe the process has not progressed far, it corresponds with t so-called 'mastitis.' Keynes gives a similar explanatic and mentions the presence of laminated plugs of keratin epithelium in the orifices of the main ducts as a contributo factor. Bagg (1926) has also undertaken experimental w with mice to endeavour to determine whether functio disturbance may have some causative relationship with onset of mammary cancer. This, in brief, consisted rapid breeding of a number of groups of animals, none which was permitted to suckle its litters, being re-ma immediately. Marked stasis in the ducts was ther produced, and in a number of cases artificial stasis was brought about by ligation of the duct orifices. The incid of mammary cancer amongst these animals was found t enormously greater than in the control groups. For exan in one group of 15 mice subjected only to rapid breed 13 developed mammary cancer, a rate of 87 per cent. compared with 5 per cent. in the controls. These re were obtained after about 8 to 12 months."

APPLICATION OF IRRITANT IN VARIOUS REGIONS

The association of carcinoma with chronic infected surfaces, with persistent sinuses, and the passage of infected mucus or frank pus prolonged period over a surface like the cervix is well known. The growth-stimulating prope of the infected secretions is again being recogn and even employed therapeutically, as in the Win Orr treatment of osteomyelitis.

In the *mouth*, the jagged tooth and ill-fi denture are undoubtedly of importance in respe the localisation by trauma of the carcinoma change in a diffuse leukoplakia. I would st however, the importance in conversion of the mucinous film which lies around the neck of the and the insoluble exudates of the pyorrhœic m The dentures of a series of patients will almost al be found to be covered by a thin slimy pellicle is insoluble in water and is difficult to remov friction of a brush but is soluble in ether and d pears readily in an alkaline solution. Where in quate attention is paid to the cleanliness of the m

THE RELATIONSHIP OF
RT SIZE AND BODY BUILD TO
ARDIOVASCULAR EFFICIENCY.

H. L. Burton, M.B. Lond.,
SQUADRON LEADER, ROYAL AIR FORCE.

a previous paper [1] on the Size of the Healthy , and its Measurement, the following conclusions reached.

ation of the apex-beat by palpation is the most e clinical method of measuring the heart, and orthophy is the simplest and most accurate radiological d.

most reliable index of heart size is its total transverse ter, which varies directly with body-weight and ely with height at any given weight.

normal transverse diameter may be predicted with nable accuracy from body-weight for those whose t is ideal for weight. In others, both height and t must be taken into account in predicting heart

e observed transverse diameter expressed as a rcentage of the predicted normal is the best way of ating heart size, but measurements cannot be applied rule-of-thumb method in separating healthy from sed hearts, and must be considered in relation to the al data. In borderline cases changes in the shape of heart silhouette are likely to be of more value than surements.

the present paper a larger series of cases have taken (223 compared with 116) in order to see far these conclusions can be confirmed and at same time to investigate the relation, if any, ween total transverse diameter of the heart, body ld, and cardiovascular efficiency.

rthodiagrams were made in the erect posture, no case was accepted unless the two independent lines of the heart agreed within 4 mm. In practice iscrepancy as much as this rarely occurred. These ords were of healthy adult males aged 18–40 years, whom neither medical history nor clinical examinan of the heart revealed any evidence of cardiac ease, past or present. The urine was normal in cases. They included 40 candidates for cadetship, civil aviation B licence cases, 22 serving officers, candidates for short service flying commissions, candidates for stores commissions, 18 airman ndidates for flying, 10 reserve officers, and 18 misllaneous cases, and the average age in each weightoup of 5 kg. was between 23 and 26 from the -54 kg. group to the 75–79 kg. group. The 80–84 kg. oup averaged 27, and the 85–89 kg. group 31 years age.

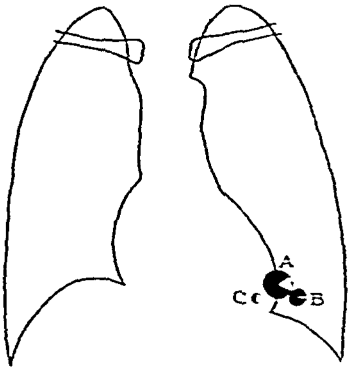
ACCURACY OF PALPATION OF THE APEX-BEAT.

In order to determine the degree of accuracy of cation of the apex-beat by palpation, a circular ad disc 1 cm. in diameter was attached to the hest wall over the estimated clinical apex prior to rthodiagraphy. It was soon found that the leftnost point on the chest wall at which a definite lift as imparted to the finger-tip was consistently xternal to the actual left border or apex of the eart as shown by the orthodiagraph. The lead was hen placed, with more satisfactory results, over the eft-most point at which a definite forward lift, at ight angles to the chest wall, was felt by the fingertip, and the term "clinical apex" is used in the following paragraphs to indicate this point. Lift is still imparted to the finger-tip in most cases 0·5 to 1 cm. further out than this, but is then oblique in direction instead of purely forward.

The first 60 cases were excluded to minimise errors in technique, and a series of 100 consecutive cases then gave the following result.

In 40 per cent. the clinical apex as marked on the chest wall corresponded to the anatomical apex as shown by X ray, and in 27 per cent. it corresponded to the left border of the heart above the anatomical apex. In 5 of these 27 cases the clinical apex was 3 cm. or more above the anatomical apex, in 12 cases 2 cm. above, and in 10 cases 1 cm. above. Measurements were taken to the nearest centimetre. The clinical apex was found to be external to the anatomical apex or left border of the heart in 25 per cent. of cases, and of these, in 19 it was 1 cm. external, and in 6, 2 cm. external. In the remaining 8 per cent. the clinical apex was internal but in only one case was the error made as much as 2 cm.

Fig. 1.



Normal orthodiagram illustrating the degree of accuracy obtainable by palpation of the clinical apex-beat. The size of the three circles indicates the relative frequency with which the clinical apex (A) agrees with, (B) lies outside, and (C) lies inside the anatomical left border or apex; the white segments indicating in each case the proportion of cases of tachycardia. Apart from this, the figure is purely diagrammatic.

In the 25 cases in which the heart was actually smaller than indicated by palpation, only one showed any degree of tachycardia. There were, however, 12 cases of tachycardia out of the 67 in which palpation and X ray agreed, and four cases out of the eight in which the heart size was underestimated.

At first sight these figures appear to conflict with the clinical experience that marked tachycardia or *tumultuous action of the heart is liable to cause over*-estimation of heart size by palpation, but there were no cases of extreme tachycardia or marked tumultuous heart action in the present series. It is also probable in such cases that if care is taken to feel the apex with the palm of the hand prior to more exact localisation with the finger-tip, as it should be in every case, fewer errors in this respect would be made.

It is interesting to note that although the clinical apex, as marked by the lead disc on the chest wall, was appreciably nearer the middle line than the more usually accepted position, the number of cases in which the lead was external compared to the number internal to the left border or apex, preponderates by 3 to 1. In other words, over-estimation of heart size by palpation is more frequent than under-estimation. It appears reasonable to assume that errors of as much as 2 cm. outside or inside the left border or apex are of rare occurrence in palpation of the normal heart, and that in over 90 per cent. the error is 1 cm. or less, provided that the selected point is the left-most at which forward thrust can be felt by the finger-tip. These points are summarised in Fig. 1.

of new bone, may apparently precede the later development of traumatic sarcoma."[42]

It would be unwise to digress at this point to discuss the effect of the retained element in menstrual blood in stimulating the growth of the fertilised ovum or of the action of the viscous secretion which covers the healthy granulating wound. In both situations there are many close resemblances, including glycolysis, to the process of cancer development. Fortunately, in the vast majority of instances, differentiation sets its seal upon the embryo and upon true repairing tissue. The slowness of carcinogenesis and its imperviousness to the differentiating influences, by reason of the surrounding fibrosis and capillary thrombosis during the critical evolutionary period of change in metabolism, render it woefully inveterate.

Substances Favouring Cell Growth.

The oleaginous medium is of importance chiefly because it acts as the excipient for the contained irritants. It has, however, certain auxiliary properties to which brief reference should be made.

The carcinogenetic agents which have been specially analysed have been found to possess some degree of activity as keratin solvents. Because of their oily nature they mix with the natural oils of the epithelial surfaces and in course of time reach the papillary lymphatics. Their insoluble nature leads to blockage of these delicate channels, and this is a possible explanation of the lymph stasis and papilloma formation which has been so cogently stressed by Sampson Handley.

Describing the surface action of fatty substances, a distinguished dermatologist states:

> "The fat is greedily taken up by the horny cells, causing them to swell up, damming back the natural evaporation and causing fluid to accumulate as far back as the papillary body, and thus on sensitive skins its application often produces a most undesirable hyperæmia and œdema.[43]

A further effect of the contact of oil with the surface of the living cell is an alteration in the interfacial surface tension of the cells with increase in their potassium content. The work of A. B. Macallum, of Toronto, on this subject deserves more attention than it has received in relation to carcinogenesis.[44]

Potassium is such a constant constituent of the living cell that all its attributes are worthy of full investigation. Its radio-activity may yet be demonstrated to be of some significance within the confines of the cell and the suggestion that it plays a part in the re-synthesis of carbohydrates[45] is worthy of consideration in relation to the comparative autonomy of the glycolising tissues.

> "Clowes and Frisbie found that rapidly growing tumours contain a high percentage of potassium and little or no calcium, whereas in old, slowly growing, relatively necrobiotic tumours the relation is reversed, the potassium decreasing greatly while the calcium increases. Beebe obtained similar results, and his analysis, supported by Clowes and Frisbie's findings, indicate the importance of potassium for cell growth. Injection of potassium salts into mice increases their susceptibility to inoculation (Clowes), while calcium decreases cancer growth (Goldzieher). Exposure of isolated cancer cells to calcium salts reduced their growth capacity when inoculated, apparently through reducing their water content. Both effects are counteracted by sodium (Cramer)."[46]

Cramer's views upon the imbibition of fluid by cells rich in salt are of great interest. He has found that the water content is highest in rapidly growing cells and lowest in the slowly growing tissues. Cells which are rich in water are the most susceptible to the action of X rays and radium.

> "The sensitiveness of a cell to these rays is dependent on the water content of its protoplasm, and since water is known to be a good absorbent for X rays and radium
> is easy to see why that should be so."[47]

The physico-chemical complex, which has b
suggested as the means by which conversio
brought about, is slow in effecting the cycle of cha
and the result may only become manifest after c
tion of the application of the potent substance. C
version being established, the transfer of the conver
cell from the epithelial zone may be determined
trauma, such as the rupture of a cyst or strain aro
the base of a papilloma. Deelman has sho
experimentally how the development of carcinom
accelerated along the lines where the trauma
scarification has been inflicted.[48] In place of
disjunction of a tumour cell, a steady infiltration
take place by a digestive action resembling th
the chorionic epithelium, the excess of lactic
from glycolysis being the probable explanatio
this capacity.

The persistence and multiplication of the conv

onsequently, although the transverse diameter approximate indication of the heart size, it by eans affords an exact estimate of it, and this ally applies to those of abnormal build. An e's heart is usually larger than that of a seden- vorker, and, taking all these factors into con- tion, we are of the opinion that for healthy between the ages of 18 and 40, a range of per cent. of predicted normal transverse dia- for any weight is a nably accu- standard of ality. As xample, in 1, if the it is 70 kg., cted trans- diameter is cm.. and ld not be r 10·8 nor e 13·2 cm. s unduly tall ort for their ht should be n special sideration. an instance of this, the unduly tall individual lly has a heart of smaller transverse diameter one of average build, and consequently in such a , if the transverse diameter is found to be +10 cent. of predicted normal, it is suggestive of nological enlargement, if from the previous history, its, and clinical findings, the heart is suspected to abnormal. The deciding factor, however, in all derline cases is the shape of the heart outline and cular pedicle as determined by the oblique views well as the antero-posterior.

CARDIOVASCULAR EFFICIENCY.

t is the general consensus of opinion that no lly satisfactory system of gauging cardiovascular fficiency exists. Various methods based on altera- ions in blood pressure and pulse-rate, lying and tanding, with or without various amounts of exer- ise, have been devised, mainly by American bservers,[5–8] but they do not, in our opinion, show ny outstanding advantage over the methods em- loyed in the Royal Air Force since its inception in 1918, and all of them take longer to apply. Estima- ion of cardiovascular efficiency of the healthy male in the Royal Air Force is based on a consideration of the pulse-response test, the 40-millimetre test, and the blood pressure. The two former have been described elsewhere,[9] but a brief résumé at this stage is necessary in explanation of the tables shown.

The *pulse-response test* shows the degree of reaction to the assumption of the erect posture as well as to mild exercise. It consists of taking (1) the steady sitting pulse; (2) the pulse-rate on the assumption of the erect posture, the degree of rise indicating the efficiency of adjustment to this position; (3) the steady standing rate; (4) the pulse-rate immediately after exercise performed by placing one foot on a chair and rising on to it 5 times in 15 seconds; (5) the number of seconds required for the pulse to return to the steady standing rate. The pulse-rate per minute is calculated from the number of beats in five-second intervals, and a stop-watch is necessary for the accurate performance of this and the following test.

In the *40-millimetre test* the subject blows up a column of mercury in a U-tube manometer to a pressure of 40 millimetres, and holds it there as long as possible. The first figure shown is the sitting pulse (number of beats in five seconds) before the commencement of the test, and the succeeding figures show the number of beats for each successive five-second interval (Table II.). The important part of the test is the behaviour of the pulse rather than the mere duration of the test, as the average young adult can usually average over 60 seconds, but an unchanged pulse throughout, or one that does not rise by more than 12, or at the most 24, beats per minute, has proved in the Royal Air Force to be a valuable indication of cardiovascular efficiency.

In measuring the blood pressure, the beginning of the fourth phase is taken as the diastolic pressure.

TOTAL TRANSVERSE DIAMETER OF THE HEART IN RELATION TO HEIGHT AND WEIGHT.

Table I. shows the relation between body-weight and total transverse diameter of the heart (T.D.) in the whole series. Figures in italics are those obtained in the previous series.[1]

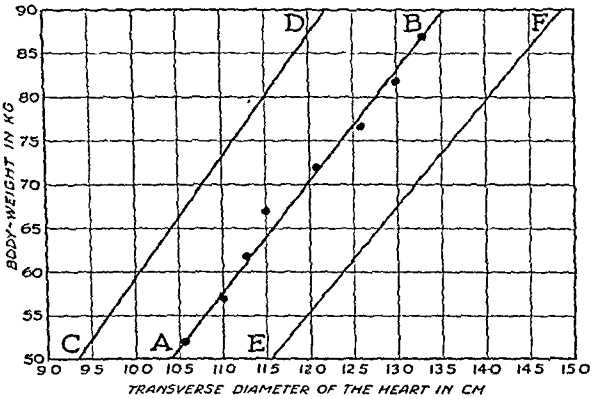
TABLE I.—*Relation of Transverse Diameter of the Heart and Body-weight.*

Weight groups (kg.)	50–54	55–59	60–64	65–69	70–74	75–79	80–84	85–89
Cases (223) ..	17	43	51	39	33	19	12	9
Average T.D. (cm.) heart .	10·6	11·0	11·3	11·5	12·1	12·6	13·0	13·3
	10·8	*10 9*	*11 2*	*11·6*	*12·1*	*12·2*	*13 4*	

Fig. 2 shows that the increase of transverse diameter is practically uniform with increase of body-weight, and for purposes of prediction can reasonably be taken as a straight line AB. Lines CD and EF show the lower limit (−10 per cent.) and the upper limit (+10 per cent.) respectively of the given transverse diameter at any weight.

The transverse diameter of the heart was found to vary inversely with height in all weight groups up to the 75–79 kg. group—i.e., those cases above the average height in each weight group had a smaller transverse diameter, and those cases below the average height had a larger transverse diameter than the average for the group. In the 80–84 kg. and 85–89 kg. groups this did not apply, but the number of cases in each group—namely, 12 and 9 respectively—are too small for any conclusion to be drawn as to whether this is of constant occurrence in these groups or not. The probable explanation is that almost all subjects over 80 kg. are disproportionately heavy for their height, and the heart in these cases tends to the horizontal position, associated with the short, broad chest commonly found in these individuals.

FIG. 2.



Relation between body-weight and transverse diameter of the heart. AB is the mean normal transverse diameter, CD is the mean normal minus 10 per cent, EF the mean normal plus 10 per cent. The normal range lies between CD and EF. *The dots represent the mean transverse diameter of each 5 kg. weight group of the present series.*

BODY BUILD.

In the study of body build, use is made of tables showing the ideal height and weight for any given age. The tables most generally used are those prepared from the American medico-actuarial tigations. These tables show height in sho weight inclusive of indoor clothing, and tables are available for both sexes. There are tables available based on medical insurance ex tions in Great Britain: (1) those of the Scottish L Assurance Co., which do not, however, differen the sexes; and (2) tables prepared from re supplied by seven important British insura offices, compiled from 28,697 medical examina for life assurance in 1921 and 1922,[2] and c males only. The weights are somewhat le those of the Scottish Life, and these again are than the American figures. As this rather sugg that actual weights and heights had been u though no definite information appeared to be ava able on this point, some 2000 cases, aged 18- examined at the Central Medical Establishment Royal Air Force, whose exact weight and he were known, were analysed by the statistical bran of the Air Ministry.

The figures were found to be of sufficient size f the compilation of a table showing the variation o weight and height for each year of age betwe 18 and 25. Over this range it was found that th weight at any given age and height agreed so closely with the figures of the British Life offices as to war rant the assumption that they represent a reasonably accurate picture of actual stripped weight and heig The weights in the Royal Air Force series for an given height and age are the higher of the two bu the discrepancy was usually below 1 kg., and th could be reasonably expected in view of the better physique of the present series compared to the population as a whole.

Using the figures of the British Life offices, th whole series was divided into three groups: (a) tho over 5 cm. too tall for their weight and age (slende build); (b) those within 5 cm. of ideal height fo weight (average build); (c) those over 5 cm. too shor (thick-set build). The 10 cm. allowance made i group (b) corresponds to an average variation i weight of 6–8 kg. at any given height.

BODY BUILD AND HEART SIZE.

In the 223 cases, 78 were in group (a), 99 in (and 46 in (c).

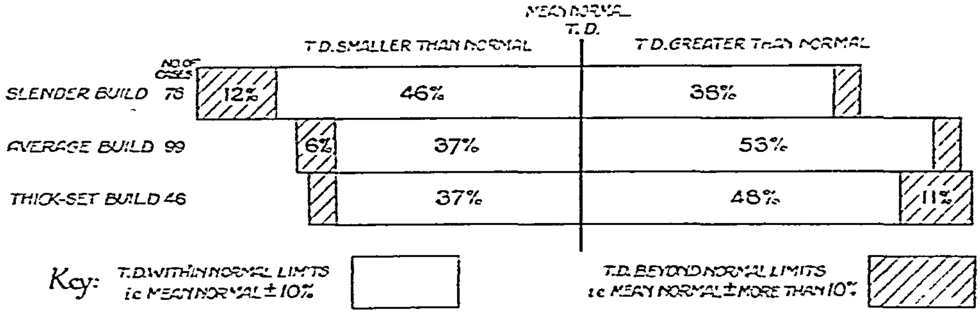
In group (a) (slender build) the transverse diame of the heart was, in 84 per cent. of cases, within t normal limits—i.e., ±10 per cent. of mean norma shown in Fig. 1, and 12 per cent. had abnorma small hearts—i.e., below −10 per cent. In group (average build) 90 per cent. were within nor limits. In group (c) (thick-set build) 85 per ce came within normality, but there were 11 per ce of abnormally large hearts.

In the total series 87 per cent. were within norma limits, 8 per cent. having abnormally small an 5 per cent. abnormally large hearts.

Fig. 3 illustrates these points, the main featur being the preponderance of abnormally small heart in the slender type and of abnormally large hearts i the thick-set type.

Bardeen [3] and Eyster [4] have produced formulæ f calculating transverse diameter from age, height, an weight, but when the many factors affecting hea size as expressed by transverse diameter are co sidered, it is doubtful whether such elaborate metho are required in practice. The body build, shape the chest, and height of the diaphragm, are all facto in determining whether the lie of the heart be of th vertical or horizontal type, irrespective of actual siz nsequently, although the transverse diameter pproximate indication of the heart size. it by ans affords an exact estimate of it, and this lly applies to those of abnormal build. An 's heart is usually larger than that of a seden- orker. and, taking all these factors into con- ion. we are of the opinion that for healthy between the ages of 18 and 40, a range of per cent. of predicted normal transverse dia- for any weight is a ably accu- tandard of ality. As xample, in 1, if the t is 70 kg., cted trans- diameter is cm., and d not be r 10·8 nor e 13·2 cm. s unduly tall ort for their ht should be n special sideration. n instance of this, the unduly tall individual lly has a heart of smaller transverse diameter one of average build, and consequently in such a , if the transverse diameter is found to be +10 cent. of predicted normal, it is suggestive of ological enlargement, if from the previous history, its. and clinical findings, the heart is suspected to abnormal. The deciding factor, however, in all derline cases is the shape of the heart outline and cular pedicle as determined by the oblique views well as the antero-posterior.

FIG. 3.



Relation between transverse diameter of the heart and body build. Percentages are omitted from the smaller spaces for the sake of clarity.

CARDIOVASCULAR EFFICIENCY.

t is the general consensus of opinion that no lly satisfactory system of gauging cardiovascular fficiency exists. Various methods based on altera- ions in blood pressure and pulse-rate, lying and tanding, with or without various amounts of exer- ise. have been devised. mainly by American bservers,[5–8] but they do not, in our opinion, show ny outstanding advantage over the methods em- ployed in the Royal Air Force since its inception in 1918, and all of them take longer to apply. Estimation of cardiovascular efficiency of the healthy male in the Royal Air Force is based on a consideration of the pulse-response test, the 40-millimetre test. and the blood pressure. The two former have been described elsewhere,[9] but a brief résumé at this stage is necessary in explanation of the tables shown.

The *pulse-response test* shows the degree of reaction to the assumption of the erect posture as well as to mild exercise. It consists of taking (1) the steady sitting pulse; (2) the pulse-rate on the assumption of the erect posture, the degree of rise indicating the efficiency of adjustment to this position; (3) the steady standing rate; (4) the pulse-rate immediately after exercise performed by placing one foot on a chair and rising on to it 5 times in 15 seconds; (5) the number of seconds required for the pulse to return to the steady standing rate. The pulse-rate per minute is calculated from the number of beats in five-second intervals, and a stop-watch is necessary for the accurate performance of this and the following test.

In the *40-millimetre test* the subject blows up a column of mercury in a U-tube manometer to a pressure of 40 millimetres, and holds it there as long as possible. The first figure shown is the sitting pulse (number of beats in five seconds) before the commencement of the test, and the succeeding figures show the number of beats for each successive five-second interval (Table II.). The important part of the test is the behaviour of the pulse rather than the mere duration of the test, as the average young adult can usually average over 60 seconds, but an unchanged pulse throughout. or one that does not rise by more than 12, or at the most 24. beats per minute, has proved in the Royal Air Force to be a valuable indication of cardiovascular efficiency.

In measuring the blood pressure, the beginning of the fourth phase is taken as the diastolic pressure.

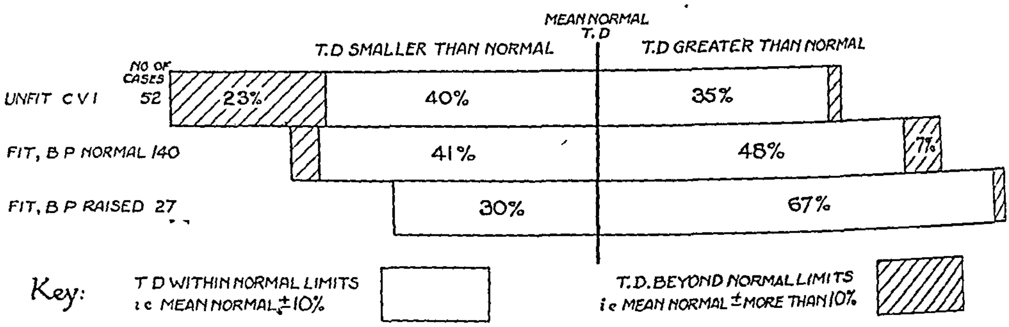
This is the point at which the clear sound heard with the stethoscope over the brachial artery changes to a faint thud prior to cessation of all sound.

The criterion as to whether an individual showed cardiovascular inefficiency or not was based on the Royal Air Force standards—i.e., whether he was, as regards his cardiovascular system, fit for Service flying.

The disproportionate number of cases of blood pressure of 140/90 and above in group (c) (thick-set build) seemed to justify special consideration of this type of case, as there were 27 in the whole series, and 14 of these occurred among those of thick-set build. We do not suggest that these raised blood-pressure cases are pathological. They are mainly single examinations, and in our experience such cases of raised blood pressure are usually lower when examined elsewhere than at the Royal Air Force Medical Board, where there is usually a pronounced emotional factor. In no case was there any clinical evidence of hypertrophy of the left ventricle, and in only one case was the heart shown by X rays to be beyond the upper limit of normality, whereas in the cardiovascularly efficient cases with normal blood pressure there were 10 out of 140 beyond that limit.

An interesting point is the rarity of blood pressures of 140/90 and over combined with cardiovascular inefficiency (C.V.I.). There were only four of such cases in the whole series, and for purposes of simplicity they have been omitted from the following table (II.), which shows the figures of the present series compared with those of 2413 fit pilots in the Royal Air Force examined in 1930.[10] The increased pulse pressure of the cases of cardiovascular inefficiency is due solely to the rise in systolic pressure, the diastolic remaining practically the same. This is the typical emotional response normally met with in this type of case, and is present to a less extent on a first examination of fit candidates, whose blood pressure averages 130/79 compared with the R Air Force pilot figure of 124/78.

FIG. 4.



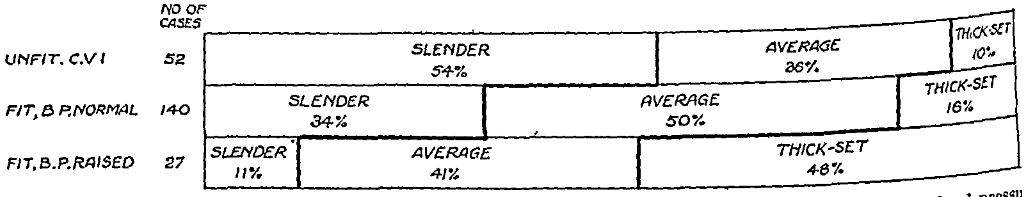
Relation between transverse diameter of the heart and cardiovascular efficiency. Percentages are omitted from the smaller spaces for the sake of clarity. C.V.I. =cardiovascular inefficiency. B.P. =blood pressure.

CARDIOVASCULAR EFFICIENCY AND HEART SIZE

Both Smith[11] and Meakins and Gunson[11] f that soldiers with symptoms of effort-syndrome h hearts whose transverse diameter was on the average 0·7 cm. smaller than the mean value of Dietlen's tables. Our figures show that the average transverse diameter of cases of cardiovascular inefficiency is 0·3 cm. below our own mean normal. When it is borne in mind that all cases were entirely symptomless, and would not have presented themselves for a medical examination reputed to be an unusually strict one unless they were fairly confident as to their medical fitness, the discrepancy is not marked. It seems probable that the effort-syndrome cases u war are recruited largely from the symptomless cardiovascular inefficients of peace time.

The preponderance of abnormally small heart among cases of cardiovascular inefficiency (23 p cent.) is in marked contrast both to the percenta found in the cardiovascular efficient type (4 p cent.), and to their complete absence among of raised blood pressure. These results are sh graphically in Fig. 4.

FIG. 5.



Relation between body build and cardiovascular efficiency. C.V.I. =cardiovascular inefficiency. B.P. =blood pressure.

CARDIOVASCULAR EFFICIENCY AND BODY BUIL

Smith[11] in his effort-syndrome cases found 65 per cent. were below normal weight. As n be expected from the preceding discussion, ther close relationship between slender build and ca vascular inefficiency. Out of the 52 cases o latter, 28, or 54 per cent., were more than 5 cm tall for their weight, and this figure rises to 8 cent. if actual ideal height for age and weig taken. The thick-set type is just the reverse of the characteristic feature of the group being the percentage of cardiovascular efficients and cas blood pressure (140/90 and over). The results own graphically in Fig. 5.

SUMMARY AND CONCLUSIONS.

he apex-beat of the heart as determined by ion coincides with the anatomical apex or left of the heart, as shown by the orthodiagram, -thirds of the cases examined. The margin of in clinical under- or over-estimation rarely ds 1 cm., and over-estimation is the more usual e two.

—In the total series of 223 cases the total trans- diameter of the heart is within ±10 per cent. edicted normal, based on weight alone, in 87 per of cases. Abnormally small hearts, as estimated heir transverse diameter, are present in 8 per . and abnormally large hearts in 5 per cent. of s.

In cases of average build, 90 per cent. of hearts within normal limits, 6 per cent. being below and r cent. above normality.

. Among those of slender build the transverse neter of the heart is below −10 per cent. of licted normal in 12 per cent. of cases.

. Among those of thick-set build the transverse meter of the heart is above +10 per cent. of dicted normal in 11 per cent. of cases.

. Height, in addition to weight, has therefore to taken into consideration in cases of abnormal ld, bearing in mind that the transverse dia- ter of the heart is usually smaller than normal those of slender build and larger in the thick-set pe.

7. All cases in which the heart size is at the border- e of normal range must be considered in relation their body build, history, mode of life, and clinical dings before they are pronounced as pathological, d changes in the heart silhouette are of more value such cases than measurements.

8. The relatively high percentage of abnormally nall hearts (23 per cent.) among cases of cardio- ascular inefficiency, as gauged by Royal Air Force sts and standards, is in striking contrast to the elatively low percentage (4 per cent.) in cases of ardiovascular efficiency.

9. Minor degrees of raised blood pressure (140/90 nd over) are rarely found among cardiovascular nefficients, and are most frequent in those of thick- et build.

10. Cardiovascular inefficiency is commonest in those of slender build.

We wish to express our thanks to Squadron Leader G. S. Marshall for suggestions and execution of the diagrams, and to Miss I. M. Marshall for secretarial assistance.

TOXIC DIPHTHERIA:

COMBINED ANTITOXIN AND DEXTROSE-INSULIN THERAPY.

BY E. C. BENN, M.B. LIVERP.,
SENIOR ASSISTANT MEDICAL OFFICER;

EDWARD HUGHES, M.B. LIVERP., D.P.H.,

AND

S. ALSTEAD, M.B. LIVERP.,
RESIDENT MEDICAL OFFICERS, BIRMINGHAM CITY HOSPITAL,
LITTLE BROMWICH.

IN a study of circulatory failure in diphtheria Schwentker and Noel[1] reject as contradictory and unsatisfactory no less than seven theories of its causation. With full acknowledgment of their debt to the pathological work of A. S. Warthin,[2] they conclude that "the symptoms of diphtheria intoxication are to a large part due to secondary constitutional disturbances in all of the essential body tissues." They show that (1) in the early phase of the toxæmia of diphtheria there is a rise in the blood-sugar due to an increased glycogenolysis. (2) As the toxæmia becomes more profound there is a steady decrease in blood-sugar which may result in hypoglycæmia. (3) As the specific effect of the toxin upon the tissues, including the pancreas, becomes more marked, glycogenesis is diminished owing to decreased insulin production. In consequence the blood-sugar again rises. They therefore suggest that in addition to antitoxin therapy in the severely toxic case of diphtheria, an attempt should be made to stabilise carbohydrate metabolism by the administration of dextrose and insulin. Schwentker and Noel record a short series of cases so treated with highly successful results.

A disorder of carbohydrate metabolism in toxic diphtheria has been noted by several workers. Mikami[3] found hyperglycæmia in rabbits which died within 24 hours of intravenous injection of diphtheria toxin, the hyperglycæmia reaching its maximum within three hours of injection and then gradually decreasing. He found that this hyperglycæmia could be prevented by double splanchnectomy, and he therefore assumed that it was of central origin. With a dose of diphtheria toxin not fatal in 24 hours a hypoglycæmia and diminution of liver glycogen occurred which was not prevented by double splanchnectomy. This work has been confirmed by Lawrence and Buckley,[4] and by Sweeney.[5] As far back as 1922, Lereboullet and his collaborators[6 7] showed that in a considerable proportion of cases of grave diphtheria a definite hypoglycæmia is present, while in mild and moderate cases the blood-sugar content is unaltered. Elkeles and Hermann[8 9 10] found a diabetic type of blood-sugar curve for a long period after recovery from diphtheria, and Schwentker and Noel[1] also report this type of curve. Hector[11] suggested the use of insulin in toxic diphtheria, and Kostyal[12] has employed dextrose-insulin therapy in diphtheria of all grades of clinical severity. Toomey[13] found that the use of dextrose decreased the incidence of heart-block and acute dilatation, but although in the presence of heart-block life was prolonged, none of his cases recovered.

We propose here to discuss the changes in the blood-sugar curve in diphtheria, and to present a series of cases of toxic diphtheria treated as suggested by Schwentker and Noel with dextrose-insulin in addition to diphtheria antitoxin. Another series of similar clinical severity treated in previous years with antitoxin alone is adduced for comparison.

TECHNIQUE AND RESULTS OF BLOOD-SUGAR ESTIMATION.

The method of estimation of the blood-sugar was that of Crecelius and Seifert,[14] based upon the conversion of picric acid to picramine acid. It permits of rapid colorimetric estimation, and requires only 0·2 c.cm. of capillary blood. Compared with the method of Folin and Wu, a constantly higher reading of less than 5 per cent. is shown. The blood-sugar estimations were made throughout by one of us (E. H.). The injection of adrenalin was avoided before and during the period of estimation.

As soon as possible after the admission of a patient suffering from toxic diphtheria a preliminary injection of antitoxin was given intramuscularly, and one hour later a resting blood-sugar estimation was made, followed by antitoxin and 20 g. dextrose intravenously (a sterile 50 per cent. solution at body temperature). Further blood-sugar estimations were made at intervals of ten minutes, one hour, one and a half hours, and two hours after the dextrose injection. By examination of the curve thus obtained a conclusion was reached as to the severity of the case and the need for insulin therapy. Experience has shown the greater the lag in the return of the curve to normal, the greater the toxæmia, and therefore the initial dextrose-tolerance curve was a valuable guide to prognosis. Hypertoxic cases showed a higher general level and more marked lag than the moderately toxic group. Even cases which had little or no clinical evidence of toxæmia showed a slight lag in the blood-sugar curves.

Fig. 1 shows the average values obtained in three groups, each of ten cases of faucial diphtheria, which were classified clinically as very mild, moderately toxic, and hypertoxic. It will be seen that a slight but definite lag is present in the curve representing the mild cases. All the patients in this group recovered with relatively small doses of antitoxin and without obvious complications. The graph of the moderately toxic cases shows a more definite lag at the end of the same period, while the curve of the hypertoxic group shows a higher general level and a more marked lag than either of the other groups. In the most severely toxic group a lag was persistently present in the dextrose-tolerance curves for an average of 20 days in those cases which recovered. The maximum duration of this diabetic type of curve was 44 days in one patient of Group III. In the moderately toxic group a "lag curve" was found on an average for seven days.

Only three of the hypertoxic cases showed a preliminary ("resting") blood-sugar content of less than 100 mg. per cent. The others showed an initial hyperglycæmia of varying degree, and this can be accounted for by the more advanced stage of disease on admission. In the absence of severe complications the dextrose-tolerance curves showed a progressive improvement as the patient recovered, but in those cases which had shown a profound early toxæmia and which developed severe cardiac or nervous complications, *a temporary return to the diabetic type of curve was observed at the onset of such complications.*

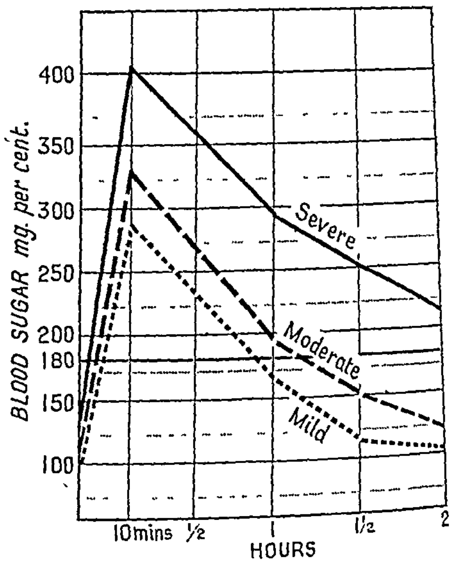
The prognostic significance of these dextrose-tolerance tests is emphasised by the occasional occurrence of a grossly abnormal curve. Such a curve usually indicates a hopeless outlook, and an example is given in Fig. 2.

The effect of insulin upon the diabetic type of curve in toxic diphtheria is to give a reading approximating more closely to the normal throughout the curve. In Fig. 3 are two curves which were obtained from a patient on consecutive days and in similar circumstances, with the exception of the administration of insulin before the giving of dextrose in curve B.

PRACTICAL APPLICATION.

Thus the evidence brought forward above conf the work of Schwentker and Noel[1] on the car- hydrate metabolism in toxic diphtheria. The charac of the dextrose-tolerance curve varies with the cli severity of the case. The amount of lag is direct proportional to the degree of toxæmia; in the mil

FIG. 1.



Average blood-sugar curves in three groups of cases

cases there is only a slight deviation from the norm curve, but in the moderate and severe grades toxæmia the curve becomes progressively diabe in character. The practical value of attempting correct the disturbance of carbohydrate metabol in toxic diphtheria may be judged from a compari of the two series of cases detailed below. In or to facilitate comparison as to the clinical severity the two groups, the short classification of fau diphtheria by Bie[15] has been adopted. Briefly t is as follows:—

A. Cases of *slight severity:* membrane *not* fully cove the tonsils; post-nasal catarrh occasionally; fœtor or sl peri-adenitis (only exceptional).

B. Cases of *moderate severity:* membrane covering tonsils and the palatine arches or the tip of the uv post-nasal catarrh; fœtor and a slight degree of adenitis frequently present; exceptional only are minuria and other signs of toxæmia, and a more ma degree of peri-adenitis—e.g., glands of "plum" or " egg" size.

C. *Severe cases:* membrane covering the uvula and palate, and frequently the hard palate also, or the b mucous membrane or posterior pharyngeal wall; post- catarrh and fœtor the rule; albuminuria frequent; of toxæmia and very marked peri-adenitis.

Needless to say, no clinical classification, w must necessarily be based upon anatomical exter membrane, can be completely satisfactory. subtle but vital factor of toxæmia is always imposs of classification. In Bie's classification larynge diphtheria and post-nasal diphtheria without visi membrane are not included. In both our grou cases with a laryngeal element and those endi fatally within 48 hours of admission to hospital ha been excluded.

Most of the cases in the two series discussed bo fall into Group C. A few were in Group B, and so were more appropriately graded as B–C, bei intermediate in clinical severity between the t grades. Serial electrocardiographic records w ıed in nearly all the dextrose-insulin group, imilar records exist for many of the controls. electrocardiographic work will be separately ibed by one of us (S. A.).

XTROSE-INSULIN THERAPY AND ITS RESULTS.

Immediately on admission: (*a*) Intramuscular tion of antitoxin (32,000 to 56,000 units). reliminary blood-sugar estimation.

) One hour after admission: (*a*) Intravenous tion of antitoxin (32,000 to 100,000 units). ntravenous injection of dextrose (20 g. of rose in 50 per cent. solution). Serum and dextrose given together with several 20 c.cm. syringes *very ly* at 37° C. The serum is in concentrated form undiluted.

) Ten minutes after intravenous dextrose, second d-sugar estimation.

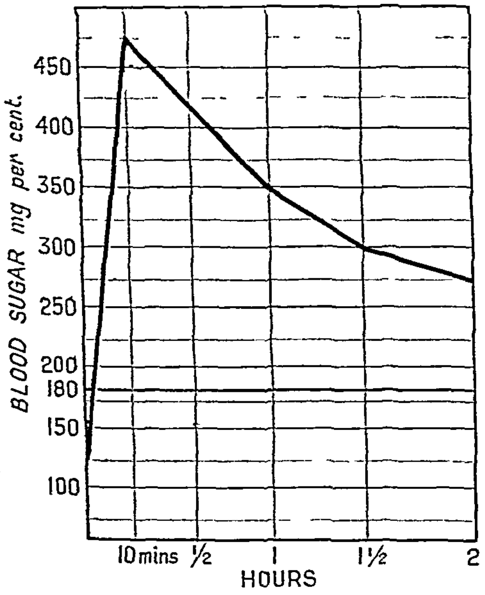
4) One hour after intravenous dextrose, third d-sugar estimation.

5) One and a half hours after intravenous dextrose, rth blood-sugar estimation.

6) Two hours after intravenous dextrose, fifth od-sugar estimation.

7) If the two-hour blood-sugar estimation shows low return to normal a suitable dose of insulin is en intramuscularly (10 to 30 units). Subsequent atment consists in giving glucose by mouth in all es where the coöperation of the patient can be tained. Commonly, children receive, diluted in nonade, from 4 to 8 oz. of glucose by mouth daily at least the first ten days after admission, and in me cases for three or four weeks. If the patient fuses, or is unable to tolerate, glucose by the mouth, 40–100 g. in 50 per cent. solution are given intravenously during each 24 hours.

FIG. 2.

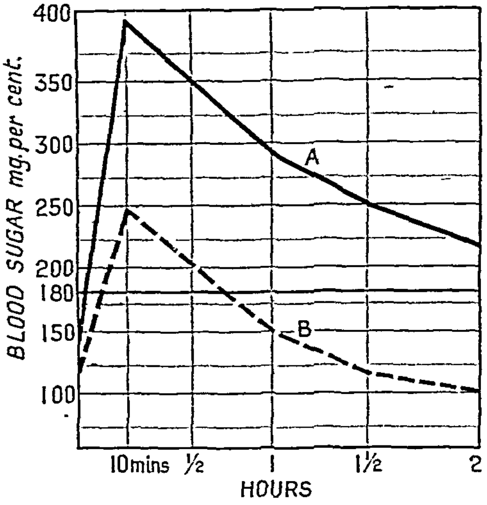


Blood-sugar curve showing pronounced lag in a severe case of diphtheria ending fatally.

Transient glycosuria after the initial dose of dextrose appears to be rare in the severely toxic cases, but was almost invariably present in the moderately toxic cases. Albumin was found in the urine at some stage of the disease in all the moderately and severely toxic cases.

Dosage with insulin depends on the degree of toxæmia as estimated by the initial dextrose-tolerance test. In accordance with the practice of Schwentker and Noel,[1] 1 unit of insulin is given for every 1 to 2 g. of dextrose, and it is then injected twice daily until the patient has passed the stage of acute toxæmia. There are often indications for large doses of insulin—e.g., 30 units twice daily—hence the possibility of hypoglycæmia must be emphasised.

FIG. 3.



Blood-sugar curves: (A) without insulin; (B) next day with 20 units of insulin.

The treatment for this condition consists in the immediate injection intravenously of about 20 g. of dextrose. Insulin therapy in these cases *must* therefore be controlled by repeated blood-sugar estimations, and in the series under consideration such tests were performed at frequent intervals. Not uncommonly, restlessness and delirium were present when the initial toxæmia was severe. Morphia in very small doses (never more than gr. 1/16th even for an adult) was found effective in combating these conditions.

It has already been stated that in the routine treatment of these cases the patient first receives an injection of serum intramuscularly. The advantages of this are that to some extent it acts as a desensitising dose for the subsequent intravenous injection; and, secondly, it provides a reservoir of antitoxin which is drawn upon during the following days when the concentration of antidiphtheritic serum in the blood due to intravenous injection is diminishing.

RESULTS.

Eighty-nine consecutive cases (Series A) were treated by dextrose-insulin therapy, and for purposes of comparison 131 similar cases (Series B) in which dextrose and insulin were not used have been taken as controls. It will be seen on reference to Tables I.–IV. that with regard to age-groups, stated day of disease at the commencement of treatment—i.e., admission to hospital—and severity according to Bie's classification, the two groups of cases are strictly comparable. Further, serum dosage in both series was approximately the same. Intravenous serum therapy was employed in all cases in the two groups with the exception of one case in Series A and two cases in Series B, the reason being that attempts to give serum intravenously were unsuccessful owing to the collapsed state of the patient.

Several important points emerge from a study of the Tables. The first is that the case-mortality in the control group was 35·9 per cent., whereas that of the dextrose-insulin group was 22·5 per cent. Since the only essential difference between the two series was the employment in the second series of dextrose-insulin therapy in addition to an average amount of antitoxin very much the same as that employed in the first series, the conclusion seems clear that the factor responsible for the striking difference in case-mortality was the stabilisation of the carbohydrate metabolism by the use of dextrose-insulin. In both groups the percentage of cases which recovered without paresis was approximately the same (Series A 20·2, Series B 19·9 per cent.), but in the dextrose-insulin group a considerably greater percentage of cases recovered with paresis during the course of the disease as compared with the control group; this difference amounts to 13 per cent. (Series A 57·3, Series B 44·2 per cent.). It is significant that this percentage difference corresponds almost exactly with the difference in case-mortality of the two groups (Series A 22·5, Series B 35·9 per cent.), indicating that this percentage of the dextrose-insulin group escaped fatal circulatory complications, but, owing to the severity of the infection, developed paralysis later in the disease.

Apparently the incidence of serum-sickness—e.g., rigors, collapse, vomiting, and rashes—within an hour or an hour and a half of intravenous injection of serum was noticeably reduced in the dextrose-insulin group; 18·4 per cent. of this group showed early serum phenomena, whereas 30 per cent. of the control series developed reactions. How far this difference is due to the simultaneous injection of dextrose, and how far to the desensitising effect of the intramuscular dose of serum which preced intravenous injection, cannot be assessed.

REPRESENTATIVE CASES.

The following are brief accounts of five cases of severe types drawn from Group A:—

CASE 1.—Girl, aged 13. Admitted on fifth day of dis Most of the fauces covered with diphtheritic membra profuse nasal discharge, fœtor, and cervical adenitis ca early bull-neck. Moderate toxæmia. No gross cha abnormality of the heart on admission. Antidiphtheri serum: 48,000 units intramuscularly; 80,000 unit venously with 20 g. dextrose one hour later. Abou dextrose-tolerance test: 80-380-230-190-135. Insulin: 20 to 4 glucose given by mouth daily. Progress satisf every day for the first three weeks. throat clear by the ninth day and obvious signs of t disappeared at the same time. Not more than a m degree of myocarditis detected clinically or electr graphically. No paralyses. Further dextrose-t curves: sixth day, 105-315-215-170-130; nint 90-356-175-115-85; eighteenth day, 125-300-190- —i.e., the gradual disappearance of the diabetic curve was simultaneous with the clinical impro Patient discharged well on the sixty-sixth day of

CASE 2.—Boy, aged 5. Admitted on second day of Marked œdema of the fauces and extensive faucial me Profuse nasal discharge and fœtor oris. Bilateral adenitis. Obviously toxic; quiet and apathetic. apparently normal on admission. Antidiphtheritic 40,000 units intramuscularly; 72,000 units intra with 25 g. dextrose. Preliminary dextrose-toleran 120-150-320-200-250. Insulin: 30 units daily for week in hospital; 20 units daily for second wee 10 units daily from seventeenth to twenty-first day. by mouth: about 5 oz. each 24 hours. Throat sixth day of disease; general condition improved first; no paraly . . . readings in conval sixth day, 105- . . . th day, 100- 125-90; fourte . . . -100-110; ni

100-260-120-90-100. Discharged well on seventy- day of disease.

E 3.—Boy, aged 18. Ill for six days on admission. , blood-stained faucial and nasal membrane; intense ; subsiding cervical adenitis. Toxæmia extreme. al signs of myocarditis present from the first. Anti-heritic serum: 48,000 units intramuscularly, and 0 units intravenously about one hour later. Dextrose-ance test, initial curve: 135-325-180-145-150. Glucose freely by mouth, and frequent intravenous injections xtrose in 50 per cent. solution. Insulin: 20-60 units for nearly three weeks. Cardiac damage severe; isive myocarditis with softening of the heart sounds riple rhythm, dilatation of the heart, and bundle-branch (E.C.G.). General condition extremely poor. Palatal, yngeal, ciliary, and diaphragmatic paralyses developed. her dextrose-tolerance tests gave results as follows: h day, 105-260-140-100-90; fourteenth day, 150-420-250-200; seventeenth day, 110-275-200-150-110. 1 the onset of bundle-branch block the readings were: 00-250-200-150 (twentieth day of disease), showing rrence of the diabetic type of curve. Convalescence very slow; in hospital 105 days.

ASE 4.—Boy, aged 10. Admitted on third day of disease. ensive deposits of membrane in the throat but no nasal harge; adenitis and peri-adenitis; fœtor oris present. rious toxæmia. Antidiphtheritic serum: 48,000 units amuscularly, and 96,000 units intravenously one hour r with 20 g. dextrose. Preliminary blood-sugar reading: -400-230-175-175. Patient refused fluids by mouth; st of the glucose given orally was vomited; daily injec-as of dextrose (20 g.) were given *intravenously*. Local ponse to serum was satisfactory, but toxæmia gradually reased, and on the eighth day of disease (day of death) trose-tolerance showed an increased lag, viz.: 120-415-)-275-230. Serial electrocardiograms showed an increasing volvement of the myocardium, and a few hours before ath complete heart-block was present.

CASE 5.—Girl, aged 4½. Admitted on fourth day. Old embrane covering most of the fauces and hard palate; pious membranous nasal discharge; breath very offensive. lateral cervical adenitis and peri-adenitis. Heart: parently normal on admission except for the tic-tac ythm. The liver was palpable 2 in. below the costal argin. Toxæmia was profound, and characterised by arked pallor and apathy. Antidiphtheritic serum: 40,000 its intramuscularly, and 96,000 units intravenously about e hour later with 25 g. dextrose. Four to six ounces of ucose taken by mouth daily. Initial dextrose-tolerance st: 100-450-330-325-300, showing a well-marked lag. isulin: 20-40 units given for first three weeks, and 10 units r following nine days. Acute toxæmia for first week with cal and petechial hæmorrhages. Gradual improvement hen began; at the seventh day of disease the blood-sugar urve was: 80-375-225-125-90. Tic-tac rhythm of the eart recurred frequently. Slight palatal paralysis only. Further dextrose-tolerance tests gave the following results: inth day, 125-425-250-200-120; twelfth day, 150-425-300-125-100; twenty-seventh day, 150-425-275-150; hirtieth day, 75-250-215-130-120. The curves were thus persistently abnormal until convalescence was fairly established in sixth week; discharged on eighty-third day of disease.

We are indebted to Dr. E. H. R. Harries, late medical superintendent of Little Bromwich Hospital, for his assistance and for facilitating the carrying out of this work; also for permission to publish the results of our investigations.

THE TREATMENT OF THE MÉNIÈRE SYNDROME BY THE ZÜND-BURGUET ELECTROPHONOID VIBROMASSAGE.

BY J. A. KEEN, F.R.C.S. ENG.,
AURAL SURGEON, LEICESTER EDUCATION COMMITTEE; AURIST, LEICESTER PUBLIC MEDICAL SERVICE.

THE treatment of the Ménière syndrome has always presented great difficulties to both physicians and otologists. Therefore any new method which has been found consistently successful in a series of cases should be placed on record.

In Ménière's classical case, first published in 1861, there was intra-labyrinthine hæmorrhage on both sides with destruction of labyrinthine function (Ménière's disease). It is now recognised that such a condition is extremely rare. For all practical purposes, patients who complain of attacks of vertigo associated with other ear symptoms are suffering from Ménière's syndrome. In contrast to "Ménière's *disease*," the affection is usually unilateral in the syndrome and the labyrinth as a rule recovers its function after the attack of vertigo has subsided. However, the hearing may remain impaired to a greater or lesser extent, and it is rare to find absolutely normal hearing on the affected side.

The condition is not very common, and I do not think that in an ordinary aural practice one would meet with more than three or four cases a year. I have looked through a file of 800 case-records of patients with ear, nose, and throat conditions and have found amongst them four cases where I made a diagnosis of Ménière's syndrome.

OTHER METHODS OF TREATMENT.

Treatment by drugs is admittedly unsatisfactory, and this partly explains the gloomy prognosis usually given to sufferers from the syndrome. One cannot consider that these patients are gravely ill; yet they are hindered from following their occupations by the constantly recurring attacks of giddiness, and they tend to get very depressed. During the acute attack the patient is kept absolutely at rest in bed, where he is allowed to assume any position which gives the maximum of relief. If vomiting be severe and threaten to exhaust him, a full dose of morphia may be given. Afterwards, we are advised to rely chiefly on the bromides, also aperients to check any tendency to constipation. Chronic pharyngitis is often present, and the patient may have to give up smoking. If he appears in low health, a general tonic is often more beneficial than sedatives. Quinine should be avoided—and this may be looked upon as a general rule in all ear affections.

The patient will get over the acute attack, even if nothing is done. His problem is to get relief from the repeated attacks and to feel reasonably certain that he can lead a normal life without the constant fear of attacks of giddiness which may surprise him at any moment. Attacks have overtaken one of my patients when he was driving a car, with great danger to himself and to others.

Counter-irritation is often recommended, and blisters or stimulating ointments may be applied behind the ear. Many years ago Dr. T. Wilson Parry recommended the insertion of a seton into the skin behind the ear; this had to be worn continuously for six months.[1] One patient was completely relieved by the Tables. The first is that the case-mortality in the control group was 35·9 per cent., whereas that of the dextrose-insulin group was 22·5 per cent. Since the only essential difference between the two series was the employment in the second series of dextrose-insulin therapy in addition to an average amount of antitoxin very much the same as that employed in the first series, the conclusion seems clear that the factor responsible for the striking difference in case-mortality was the stabilisation of the carbohydrate metabolism by the use of dextrose-insulin. In both groups the percentage of cases which recovered without paresis was approximately the same (Series A 20·2, Series B 19·9 per cent.), but in the dextrose-insulin group a considerably greater percentage of cases recovered with paresis during the course of the disease as compared with the control group; this difference amounts to 13 per cent. (Series A 57·3, Series B 44·2 per cent.). It is significant that this percentage difference corresponds almost exactly with the difference in case-mortality of the two groups (Series A 22·5, Series B 35·9 per cent.), indicating that this percentage of the dextrose-insulin group escaped fatal circulatory complications, but, owing to the severity of the infection, developed paralysis later in the disease.

Apparently the incidence of serum-sickness—e.g., rigors, collapse, vomiting, and rashes—within an hour or an hour and a half of intravenous injection of serum was noticeably reduced in the dextrose-insulin group; 18·4 per cent. of this group showed early serum phenomena, whereas 30 per cent. of the control series developed reactions. How far this difference is due to the simultaneous injection of dextrose, and how far to the desensitising effect of the intramuscular dose of serum which precedes the intravenous injection, cannot be assessed.

REPRESENTATIVE CASES.

The following are brief accounts of five cases of severe types drawn from Group A:—

CASE 1.—Girl, aged 13. Admitted on fifth day of disease. Most of the fauces covered with diphtheritic membrane, profuse nasal discharge, fœtor, and cervical adenitis causing early bull-neck. Moderate toxæmia. No gross clinical abnormality of the heart on admission. Antidiphtheritic serum: 48,000 units intramuscularly; 80,000 units intravenously with 20 g. dextrose one hour later. In dextrose-tolerance test: 80-380-230-190-135. About glucose given by mouth daily. Insulin: 20 to 40 every day for the first three weeks. Progress satisfact throat clear by the ninth day and obvious signs of tox disappeared at the same time. Not more than a mod degree of myocarditis detected clinically or electroca graphically. No paralyses. Further dextrose-tole curves: sixth day, 105-315-215-170-130; ninth 90-356-175-115-85; eighteenth day, 125-300-190-10 —i.e., the gradual disappearance of the diabetic ty curve was simultaneous with the clinical improve Patient discharged well on the sixty-sixth day of di

CASE 2.—Boy, aged 5. Admitted on second day of dis Marked œdema of the fauces and extensive faucial membrane. Profuse nasal discharge and fœtor oris. Bilateral cervical adenitis. Obviously toxic; quiet and apathetic. Heart apparently normal on admission. Antidiphtheritic serum: 40,000 units intramuscularly; 72,000 units intravenously with 25 g. dextrose. Preliminary dextrose-tolerance test: 120-450-320-290-250. Insulin: 30 units daily for the first week in hospital; 20 units daily for second week; and 10 units daily from seventeenth to twenty-first day. Glucose by mouth: about 5 oz. each 24 hours. Throat clear on sixth day of disease; general condition improved from the first; no paralyses. Blood-sugar readings in convalescence: sixth day, 105-375-270-150-125; ninth day, 100-375-145-125-90; fourteenth day, 100-250-150-100-110; nineteenth irmed the diagnosis, and who reported that two is fellow examiners had at first totally failed to the murmur and thrill correctly.

he following case is recorded because it not only rides a clear explanation of the mechanism by ch the observed thrill was produced, but also gests a possible mechanical reason for the rarity ll aortic diastolic thrills.

CASE RECORD.

he patient was a 'bus driver, aged 49. He was nitted to St. Bartholomew's Hospital under the e of Sir Percival Hartley, to whose kindness I am ebted for permission to publish the case. His nplaints were dyspnœa on exertion and swelling the feet.

istory.—On going to work on Nov. 10th, 1930, he was ted with a sudden attack of dyspnœa. This lasted for hour, and after it he came to St. Bartholomew's Hospital, ere a lesion of the aortic valve was diagnosed. His ssermann reaction being positive, he was given a course neo-arsphenamine (4·65 g.) and bismuth (8 c.cm.). He atinued at work until Jan. 10th, 1931, when he had a ond similar attack of dyspnœa, lasting again for about hour. On March 2nd, after a heavy day's driving, he ticed that he was unusually exhausted, and that his legs re swollen. Dyspnœa on exertion was now more pronounced. He attended hospital again, and was admitted March 9th.

Condition on Examination (April 13th).—The atient was lying comfortably in bed. There as no pallor or cyanosis, but slight orthopnœa was pparent. There was no increased pulsation in the eck. The chest was slightly emphysematous. A iffuse and very slight systolic cardiac impulse was isible in the fifth and sixth spaces. The apex-beat as palpable 4½ inches from the mid-line in the ixth space. The impulse was feeble and diffuse. Percussion confirmed the palpatory signs. On uscultation the first and second sounds were naudible. Coinciding with systole, as judged by the pulsation to be felt over the præcordium, there was at the apex and over the aortic base a soft, distant, blowing systolic murmur. Coinciding with diastole, there was a harsh, loud, twanging murmur accompanied by a thrill. This thrill was best felt over the aortic base and the upper end of the sternum. The diastolic murmur was loudest here also, but was conducted along the left border of the sternum to the apex in addition. Both thrill and murmur were easily definable, and could be accurately timed in relation to the præcordial impulse and the carotid pulse. The description of the diastolic murmur as a harsh, loud, twanging sound occurs in my notes made at the time.

The pulse was of the water-hammer type. The blood pressure was 134/30. The electrocardiograph showed a regular sinus rhythm, left-sided preponderance, inversion of "T" in lead I, and slight widening of the Q R S complex to 0·19 of a second. A radiogram taken on March 17th showed a general enlargement of the heart, which was slightly displaced to the right, and also evidence of a small, left-sided pleural effusion.

The Wassermann reaction was positive, as was the sigma reaction (16·8 units). The diagnosis was thus "syphilis of the heart with aortic incompetence and some congestive failure." The patient remained in hospital until May 2nd, when he was discharged improved. On June 25th he was readmitted with a more advanced condition of congestive failure than before. Œdema of the feet and legs, ascites, and albuminuria were present. The cardiac physical signs remained unchanged. He suffered from several attacks of acute left ventricular failure, characterised by collapse, severe dyspnœa, and a weak, rapid pulse. He died suddenly on Nov. 20th.

Post Mortem.—The heart was generally enlarged, but the left ventricle showed the greatest change. The chamber was dilated and somewhat hypertrophied, the muscle being rather friable and pale. The aortic ring was considerably stretched, easily admitting three fingers. The aortic cusps were soft, thin, and flexible along their free edges, showing no rigidity, puckering, or distortion of natural outline. At their junction with the aortic wall the commissures showed some œdema and thickening, characteristic of syphilitic infiltration, but of a very early stage. The coronary orifices were slightly œdematous. The first part of the aorta showed marked and characteristic syphilitic aortitis, with its longitudinal puckering and scarring. The changes were similar, but less marked, in the second part of the aorta.

It was clear from the post-mortem examination that aortic incompetence had been present, that this was due to stretching of the aortic ring from syphilitic aortitis, and that the aortic cusps were free, flexible, mobile, and not of themselves responsible for the valvular leak.

DISCUSSION.

Thrills and murmurs are caused by vibrations set up either in the blood stream or in the cardiac structure, or in both. Murmurs frequently occur without thrills; but thrills never occur without murmurs, although in some cases of mitral stenosis a low rumbling diastolic murmur is less easy to distinguish than is the associated coarse thrill.

Whether a thrill will be palpable in any case will depend upon the presence of vibrations sufficiently coarse to be detected by the hand. The difference in sensitivity between the sense organs of hand and ear will therefore be the measure of the probability of the existence of a palpable thrill when a murmur is present. In aortic regurgitation a murmur is almost invariably present, while a thrill is almost always absent. The common causes of aortic regurgitation are acute rheumatism, syphilis, arterio-sclerosis, and septic endocarditis. The valvular conditions generally accompanying each of these is worth recapitulating. In the rheumatic type, the valve cusps are thickened, sclerosed, and retracted. The cusps are stiff, fibrosed, and even calcified. In arterio-sclerosis, stiffening and calcification of the cusps is also present. Septic endocarditis is almost invariably superimposed upon an already diseased valve. Syphilitic aortic regurgitation results either from the invasion of the cusps at their commissures, infiltration of their substance, with subsequent scarring, thickening, and deformity, or from stretching of the aortic ring from syphilitic aortitis. In the latter case it is rare for the valve cusps themselves to escape.

In the case described the aortic regurgitant diastolic thrill was due to the fact that the aortic ring was stretched and the valve cusp edges free and flexible. It is suggested that at the commencement of diastole and during early diastole the regurgitating blood stream was so opposed to the free taut edges of the flexible cusps that the latter vibrated coarsely, like the reed in a clarinet, and gave rise to a "twanging" murmur and the marked diastolic thrill. If the cusps had been stiff, if their edges had been thickened, if their relation to the direction of the opposing blood stream had been slightly different, or if the rate of this stream had been other than it was, a murmur would doubtless have resulted, but not a harsh musical note, nor the accompanying coarse thrill.

Reference to the clarinet, or other such wind instrument, shows us what conditions are necessary this measure; the Ménière attacks in this case had been so frequent and obstinate that an operation on the labyrinth would probably have been suggested nowadays. Parry explains that the seton acts by continuous counter-irritation, and suggests that there is a direct action on the vasomotor system of a special skin area and that this action reflexly influences the vasomotor nerves of the labyrinthine vessels. It is probable that this barbarous method of treatment was used in a good many cases in the past.

A great advance in therapeutics was made when it became recognised that attacks of labyrinthine vertigo were frequently due to unilateral Eustachian obstruction, as Mr. Sydney Scott so clearly demonstrated. Many patients have been cured by the systematic use of the Eustachian catheter.[2]

VIBROMASSAGE.

In my experience, the quickest and most certain way of arresting the attacks of vertigo is to apply the Zünd-Burguet electrophonoid vibromassage. My main purpose in writing this paper is to make it more widely known how very successful the vibromassage by sound stimulation can be in relieving vertigo, and to induce others to give this treatment a trial

I began to use the Zünd-Burguet electrophone in 1922, after having had the privilege of seeing Dr. G. C. Cathcart use the treatment in London and also of seeing M. Zünd-Burguet in Paris. In their respective books on the treatment [3] [4] it is stated that in favourable cases feelings of giddiness disappear, while hearing is improved and tinnitus relieved. However, it is not specially mentioned that one can relieve the Ménière symptom-complex, and I approached these cases very diffidently at first. After a time it became obvious to me that the vertigo responded more quickly to the electrophone than any other symptom. While one has many disappointments as regards relief of deafness and tinnitus, the patient with the typical Ménière syndrome can almost certainly be promised relief.

I have only found one previous reference to "Ménière's disease" treated by the electrophonoid method—viz., one case reported by Dr. A. Ferguson in 1927.[5] From a list of about 20 personal cases treated by the Zünd-Burguet method alone, I selected seven for following-up and for a more detailed consideration of symptoms. It is unnecessary to give the clinical histories of these cases here, but it will be sufficient to state that the end-results were extremely satisfactory. After intervals varying from two to eight years, during which time no medicinal or other treatment was given, these patients have remained free from attacks of vertigo, although the other two symptoms of the triad—viz., deafness and tinnitus—were not necessarily relieved.

As the obstinate and chronic nature of this complaint is so constantly stressed in medical text-books, I can only attribute these results to the treatment which was given, and I should find it difficult to invoke any question of spontaneous subsidence of the attacks.

For details about the electrophonoid vibromassage treatment, for a description of the apparatus, and for an explanation of its action on the ear organ, I refer the reader to M. Zünd-Burguet's "Principes d'Anacousie" [4] and to Dr. Cathcart's book [3] and articles. As nerve deafness and tinnitus are often benefited, it seemed a natural step to use the treatment in such a purely labyrinthine disturbance as the Ménière symptom-complex.

I must emphasis a few points in connexion with t electrophonoid vibromassage which apply particula when this treatment is given to a patient w complains of Ménière attacks.

As a general rule, the treatment is applied to one e only, after one has decided where the disturbance is. T treatment may be begun as soon after an attack as o wishes. At first the patient may be still very unstead and may have to be led to one's consulting room. Af four or five treatments the unsteadiness has gone and h will come by himself. The heaviness in the head an indefinite neuralgic pains disappear, the tinnitus may g the hearing may or may not improve, but the vertig definitely vanishes and does not recur in the majority o cases.

At the first treatment it is necessary to start with ver low intensities, otherwise vertigo may be caused at the tim and the patient loses confidence. I begin with a treatme of about two minutes, but after three or four sittings th full six minutes' treatment may be given. The treatment are either daily or at longer intervals—e.g., four during week. A course of treatment for a case of Ménière' syndrome may require 10 or 15 or 20 attendances, but hardl ever more, as the response is remarkably quick.

If attacks of vertigo begin to appear again, a secon course of treatment may be given after three or four month or after longer intervals. Among the seven cases mention previously only one required a second course of treatme for recurring attacks of giddiness.

Serious labyrinthine operations are sometim advised when a patient is found to suffer from inc able vertigo, or remains subject to constant atta for years.[6] [7] [8] I submit that no case should e be allowed to undergo operation until the Zü Burguet electrophonoid treatment has been give thorough trial. In my experience it has proved be a most valuable remedy for the relief and cure the Ménière syndrome.

AORTIC DIASTOLIC THRILLS.

REPORT OF A CASE.

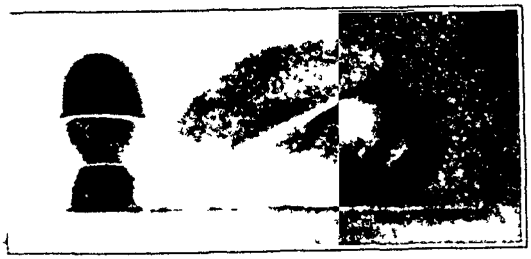
BY GEOFFREY BOURNE, M.D., F.R.C.P. LON
ASSISTANT PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITA
PHYSICIAN TO KING GEORGE'S HOSPITAL, ILFORD.

MURMURS and thrills, as physical signs, ar often capable of definite and clear explanation, when full post-mortem correlation is possible. is especially true of aortic diastolic thrills.

Gee [1] states: "There is no kind of valvular d of the heart which may not produce a thrill"; White,[2] in his book, "Heart Disease," states: diastolic thrill is very rare except for that d mitral stenosis. At the base of the heart, bes along the left border of the sternum, a diastolic with marked aortic regurgitation occurs with infrequency."

It is possible that, by errors in timing, a c number of such diastolic thrills are missed by labelled systolic, and are wrongly regarded as cating aortic stenosis. The first patient exhi an aortic diastolic thrill observed by the write an out-patient at the East London Hospit Children, Shadwell. This child was sent to Dr. Drysdale, then examining for the L.R.C.P.,

, latter condition, found frequently in weavers, ften spoken of as "weavers' bottom"—probably he moment an almost non-existent disease! It ɔmmon, I believe, in harvesters, from the friction jolting of the iron seat of the reaping machine. he accompanying photograph illustrates a case on ch I recently operated. The patient, a man of 50, ea-captain, had this swelling hanging from the it buttock for the last 20 years. It had been gnosed repeatedly as a lipoma, and being of no



ore importance than a double chin in the wrong ace had been allowed to remain undisturbed by rgeons all this time. The operation was an easy ie, and the cyst parted company with the ischium ithout difficulty. It weighed 2 lb. 10 oz.; the rcumference was 18½ in.; and the diameters were ½ and 6 in. It was moderately filled with fluid, id gave the impression to the touch of a rubber air-ıshion; hence its presence was probably a comfort ither than otherwise, although mechanically and ɔsmetically it was a nuisance; it was tending to lose over the anus.

I report the case as one of wrong diagnosis before peration, and secondly to show to what extent a ursa may enlarge and still be absolutely painless nd without symptoms. The third point of interest n the case was the fact that the patient's Wassermann eaction had been positive 30 years ago. Syphilitic ɔursitis occurs, but is usually bilateral. The photo-raph gives a rough idea of the size in contrast with he size of a hen's egg.

SPONTANEOUS RUPTURE OF AN ABNORMAL SPLEEN.

By Wilfrid Attlee, M.D. Camb., M.R.C.P. Lond.,

PHYSICIAN TO THE KING EDWARD VII. HOSPITAL, WINDSOR.

Spontaneous rupture of the normal spleen is extremely rare, and Hamilton Bailey[1] in 1929 was able to find only 11 recorded cases of the condition. Spontaneous rupture of the abnormal spleen is less uncommon, and as M. P. Susman[2] pointed out in 1927, most of the recorded cases have been associated with malaria, typhoid fever, pregnancy, leukæmia, and septic conditions of the skin. Nevertheless it is perhaps sufficiently rare even in these conditions to warrant the publication of the following case:—

A single woman, aged 23, a post-office assistant, complained on August 11th, 1930, of swollen glands in the neck, which she had had for three or four days. She looked ill, the temperature was 99° F. and pulse-rate 80. A chain of glands was enlarged on both sides of the neck along the posterior border of the sternomastoid, and the occipital glands on both sides were enlarged. They were all hard and not particularly tender, and there was nothing obvious in the throat or elsewhere to account for them. The spleen was not palpable and the axillary and inguinal glands were not enlarged.

On August 13th she still looked ill but complained of nothing except the glands in the neck. The temperature was 100° F. and the right tonsil looked very slightly red. Klebs-Löffler bacilli were absent from a swab and the leucocyte count was 20,100. On the 15th both tonsils were enlarged and red with exudation in the crypts, and the uvula was œdematous. On the 16th the right tonsil and uvula were more swollen, and the appearance suggested the beginning of a quinsy. By the 19th the throat was less red and the organisms of Vincent's angina were reported on a swab.

On August 20th she collapsed after defæcation following a dose of Epsom salts. She looked very ill, with temperature 100° and pulse-rate 120, but complained of nothing but faintness. The abdomen was distended and tympanitic and a little tender on both sides. Sir Joseph Skevington who saw her with me found, on rectal examination, a tender spot in the pelvis, high up on the right side, and she was admitted to hospital as possibly a case of appendicitis. She improved considerably during the next two days, but the temperature continued between 100° and 101° with pulse-rate 92 to 100, and the rectal tenderness persisted.

On August 22nd Sir Joseph Skevington made a right paramedian incision for appendicectomy and the pelvis was found to be full of dark blood. The appendix was normal, as were tubes, ovaries, and uterus. Fresh blood welled down from the upper abdomen, and on exploration the spleen was found to be enlarged and ruptured. A left paramedian incision was then made in the upper abdomen and splenectomy was performed. The spleen was soft, about three times its normal size, and ruptured.

A blood count by Dr. E. C. Malden on August 23rd gave the following results:—

Red cells..	.. 2,180,000	Polymorph. ..	.. 69%
White cells	.. 21,250	Lymphocytes..	.. 26%
Hæmoglobin	.. 51%	Hyalines ..	.. 4%
		Eosinophils ..	.. 1%

On Sept. 2nd the red cells were

The New Freemasons' Hospital.—At the annual meeting of the Freemasons' Hospital and Nursing Home last week it was stated that in the past year "the present little hospital" had admitted the record number of 681 patients. It had been decided to provide in the new buildings, the dedication stone of which is to be laid by the Duke of Connaught on May 19th, a total of 180 beds, and to open two wards for small children. The naming of beds in the new hospital has been so popular that the whole of the 96 available for naming have been taken up at £1000 each. Several single-bed wards will be named at £1500 each. During the year ended with June last, a little over £106,000 had been given, with a further £29,000 to Dec. 31st. The contract for the complete hospital was £313,000, but many improvements in the original scheme have been suggested involving an additional appeal for £75,000, and it has been decided to postpone work on the western wing for the time being.

CLINICAL AND LABORATORY NOTES

THE TREATMENT OF OCULOGYRIC CRISES IN CHRONIC EPIDEMIC ENCEPHALITIS.

BY H. ASTLEY COOPER, M.B. LOND.,
ASSISTANT MEDICAL OFFICER, WEST PARK MENTAL HOSPITAL, EPSOM, SURREY.

OF the 80 patients at the West Park Mental Hospital suffering from encephalitis lethargica, 12 were found to have oculogyric crises, either alone or associated with conduct disorders. McCowan and Cook[1] found that hyoscine, gr. 1/100 hypodermically, cut short the attacks, and that *oral* and hypodermic hyoscine both reduced the incidence of attacks if given regularly. It has been our recent practice here to use tinct. stramonii, in doses up to ♏ 90 t.d.s., as the standard drug in parkinsonian cases. It has been found more efficient than hyoscine. But our experience agreed with that of Hall[2] that, though the frequency might be reduced or a particular attack cut short, no cases ceased altogether to have the oculogyric crises.

Other drugs were therefore tried: potassium bromide, luminal—alone or in combination—and impletol. The following are brief notes on the cases.

CASE 1, female. Primary attack 1921. Unable to work on account of crises. Usual incidence 7–8 days, preceded by obsessional nonsense phrases interrupting any thought. Pot. brom., grs. 10 t.d.s., stopped attacks entirely. Tinct. stramonii, ♏ 15 t.d.s., administered throughout, had no effect on the attacks.

CASE 2, female. Primary attack 1927. Moderate parkinsonism. Usual incidence of crises 2–3 days' interval. Tinct. stramonii, ♏ 60 t.d.s., improved parkinsonism markedly, but had no effect on crises. Pot. brom., grs. 10 t.d.s., reduced attacks to eight a month, but bromism stopped treatment. Luminal, gr. 1, reduced attacks to five a month. Luminal, gr. ¾ b.d., reduced attacks to four a month. The tinct. stramonii was kept constant throughout.

CASE 3, male. Primary attack April, 1923. Marked parkinsonism and frequent oculogyric attacks on admission 1927. On tinct. stramonii, ♏ 90 t.d.s., he had about two attacks monthly over two months. Reported to be his usual rate. He also frequently had outbursts of acrobatic exhibitionism. Pot. brom., grs. 10 t.d.s.; two attacks a month; no change in acrobatics. Luminal, gr. 1 nocte. two attacks and ten acrobatic attacks in month. Pot. brom., grs. 10 t.d.s.; luminal, grs. 1½ nocte; no further crises; four acrobatic attacks in month. More settled mentally. Tinct. stramonii unaltered throughout.

CASE 4, female. Primary attack 1924. Advanced parkinsonism. Oculogyric crises, three in ten days, but apparently then ran in groups. 1931: attacks alternate days, 14–15 monthly, in spite of tinct. stramonii, ♏ 90 t.d.s. Attacks could be stopped within 20 minutes by hyoscine, gr. 1/100. Pot. brom., grs. 10 t.d.s., reduced attacks to five or six a month. Luminal, grs. 1½ nocte, reduced them to nine a month. Tinct. stramonii was constant throughout.

CASE 5, female. Primary attack 1924. Advanced parkinsonism, with screaming attacks weekly. Definite oculogyric crises rare, usually fixity of eyes only. Tinct. stramonii, ♏ 90 t.d.s.; frequency of screaming attacks appeared to be less, according to notes of case, but they did not stop. Pot. brom., grs. 10 t.d.s., had no effect. Luminal, gr. 1 nocte, had no effect.

CASE 6, female. Primary attack 1920. Moderate parkinsonism. Paranoid psychosis. Tinct. stramonii, ♏ 60 t.d.s., had no effect on crises. Pot. brom., grs. 10 t.d.s., reduced attacks from seven or eight to four a month.

CASE 7, female. Primary attack 1919. Advanced parkinsonism. Usual rate of crises seven or eight a month. Tinct. stramonii, ♏ 90 t.d.s., produced no change in crises. Pot. brom., grs. 10 t.d.s.; no further crises, but patient developed spasmodic torticollis; the attacks have not recomm since discontinuing the bromide.

CASE 8, female. Primary attack 1927. Moderate pa sonism. Usual rate of crises twice daily. Tinct. stram ♏ 90 t.d.s., reduced attacks to seven a month. Pot. b grs. 10 t.d.s., reduced them to two to four a month.

CASE 9, male. Primary attack 1921. Advanced pa sonism, with maniacal outbursts in association with o gyric crises. Incidence about seven or eight a m Tinct. stramonii, ♏ 90 t.d.s., and luminal, gr. ¾ n produced no change in incidence.

CASE 10, male. Primary attack 1924. Advanced pa sonism. Fits of weeping and howling with self-mutila weekly, with oculogyric crises. Tinct. stramonii, ♏ 90 t produced no change in attacks, nor did pot. brom., gr t.d.s., or luminal, gr. 1 nocte.

CASE 11, female. No history of primary attack. O gyric crises since 1927. Moderate parkinsonism. Tw three screaming fits weekly in association with c Tinct. stramonii had no effect. Nor did luminal, gr nocte or b.d.

Summary of Cases.—Eleven cases were tried bromide or luminal. One stopped altogether, five had less frequent attacks, one of these not ha had any more attacks. These six were all simple c without behaviour disorders of a gross type in a ciation with the fits. Of the five "apache typ one was improved in behaviour and his crises cea The other four were not improved.

The cases recorded are considered to be interes as a basis for further investigation, but the seri small, and the susceptibility of these patient suggestion has been previously noted. While a si substitution of, for instance, water for hyos hypodermically may succeed in relieving sympt the patients are not usually to be deceived tw moreover, they usually hold definite ideas on merits of various drugs, and can often describe defects of new drugs as compared with prev ones. We regard the period of observation as s safeguard against suggestion effects.

My conclusion is that potassium bromide luminal are definitely useful in reducing the incid of oculogyric crises, and may occasionally them.

In view of the above results, and the heada which Case 4 has in many of her crises, impletol also tried in three cases as a means of aborting eye crisis. No effect was obtained with it, when the dose was repeated in 15 minutes. Impl therefore, is no use in oculogyric crises.

My thanks are due to Dr. Norcliffe Roberts fo interest and assistance in this work.

A VERY LARGE BURSA.

BY IAN FRASER, M.CH. BELF., F.R.C.S. ENG. F.R.C.S. IREL.,
HON. ASSISTANT SURGEON, BELFAST HOSPITAL FOR SICK CHILDREN.

ENLARGEMENT of the bursa placed over the isc tuberosities is a well-recognised entity. Irrita or intermittent pressure may cause a mild de of traumatic bursitis with resultant swelling enlargement of these bursæ. The swelling is a rule of the ordinary serous type, but in many ca solid enlargements occur, and if much surround fibrosis has taken place the operation for t removal may be a tedious and difficult dissecti latter condition, found frequently in weavers, en spoken of as "weavers' bottom"—probably e moment an almost non-existent disease! It amon, I believe, in harvesters, from the friction olting of the iron seat of the reaping machine.

e accompanying photograph illustrates a case on ı I recently operated. The patient, a man of 50, .-captain, had this swelling hanging from the buttock for the last 20 years. It had been osed repeatedly as a lipoma, and being of no

e importance than a double chin in the wrong e had been allowed to remain undisturbed by cons all this time. The operation was an easy and the cyst parted company with the ischium ıout difficulty. It weighed 2 lb. 10 oz.; the amference was 18½ in.; and the diameters were and 6 in. It was *moderately filled with fluid*, gave the impression to the touch of a rubber air-ıion; hence its presence was probably a comfort ıer than otherwise, although mechanically and metically it was a nuisance; it was tending to e over the anus.

Professeur de Clinique [illegible] l'Hôtel-Dieu, Membre de l'Académie [illegible] ne. Paris: Masson et Cie. 1931. Pp. 398. Fr. 75.

Prof. Hartmann's new work is a further testimony to the author's laudable industry. Both *minor and* major conditions are described in detail, and almost every page reveals the author's exceptional experience in this branch of surgery and his deep knowledge of the literature.

The chapter on stenosing proctitis, of which the author has had 120 cases, is a particularly notable one: the pathology is discussed in detail, together with the varying methods of treatment. Prof. Hartmann has treated 56 cases by amputation of the rectum with preservation of the sphincters; the mortality works out to 4 per cent., and the functional results appear generally to be extremely good. A bibliography of more than three pages concludes this chapter. Cancer of the rectum is the subject of an imposing essay of more than 100 pages. The perineal and abdomino-perineal excisions, together with their modifications, are discussed. Prof. Hartmann describes a perineal excision of the rectum with the removal of the sphincters and the formation of a perineal anus, slightly posterior to the normal position. Details are given of 75 cases which were followed up after this operation; a certain degree of incontinence and prolapse were not uncommon. The mortality of this operation is estimated as 14 to 16 per cent.; the late results show rather a high incidence of local recurrences which have frequently necessitated a colostomy later. It is difficult to

(*Continued from previous page.*)

attendant to wait for signs of pneumonia. If signs are waited for, then we may wait for death to occur before the signs show themselves. By some people alkaloids are ordered, one for each separate symptom. This is a bad method of treating such cases. Far better with some old and tried medicine to anticipate symptoms, and prevent worse ones occurring.

Since the exhibition of boric crystals, which are used to fill up the wound, there has not been a case at Guy's Hospital of sloughing of the wound, but if it does occur, then there are two important items of treatment. The sloughs should never be forcibly removed. Such a procedure will only lead to further infection of the wound, and perhaps the death of the patient. It is possible that this sloughing may follow the use of indiarubber drainage-tubes, for such tubes contain free sulphur, which has its uses in certain septic urinary cases, but is not wanted after prostatectomy. The second item is this: such sloughing, especially if the slough be grey or black, may indicate that the patient is dying.

Among other points mentioned in the address, Mr. Thompson said that in a certain number of cases it is important that the wife should be kept away from the patient for two or three days after the operation, and that directly the patient is to be allowed up a carefully fitted suspensory bandage should be properly applied, as it is not unknown for orchitis to occur sometime after the operation, and even when the patient has gone home.

CLINICAL AND LABORATORY NOTES

THE TREATMENT OF OCULOGYRIC CRISES IN CHRONIC EPIDEMIC ENCEPHALITIS.

By H. Astley Cooper, M.B. Lond.,
ASSISTANT MEDICAL OFFICER, WEST PARK MENTAL HOSPITAL, EPSOM, SURREY.

Of the 80 patients at the West Park Mental Hospital suffering from encephalitis lethargica, 12 were found to have oculogyric crises, either alone or associated with conduct disorders. McCowan and Cook[1] found that hyoscine, gr. 1/100 hypodermically, cut short the attacks, and that oral and hypodermic hyoscine both reduced the incidence of attacks if given regularly. It has been our recent practice here to use tinct. stramonii, in doses up to ♏ 90 t.d.s., as the standard drug in parkinsonian cases. It has been found more efficient than hyoscine. But our experience agreed with that of Hall[2] that, though the frequency might be reduced or a particular attack cut short, no cases ceased altogether to have the oculogyric crises.

Other drugs were therefore tried: potassium bromide, luminal—alone or in combination—and impletol. The following are brief notes on the cases.

Case 1, female. Primary attack 1921. Unable to work on account of crises. Usual incidence 7–8 days, preceded by obsessional nonsense phrases interrupting any thought. Pot. brom., grs. 10 t.d.s., stopped attacks entirely. Tinct. stramonii, ♏ 15 t.d.s., administered throughout, had no effect on the attacks.

Case 2, female. Primary attack 1927. Moderate parkinsonism. Usual incidence of crises 2–3 days' interval. Tinct. stramonii, ♏ 60 t.d.s., improved parkinsonism markedly, but had no effect on crises. Pot. brom., grs. 10 t.d.s., reduced attacks to eight a month, but bromism stopped treatment.
Luminal, gr. 1, reduced attacks to five a month. Lum
gr. ¾ b.d., reduced attacks to four a mon may lead

month. Tinct catheter has been removed a light
is applied round the penis, and this is removed directly the bladder has been opened. When the bladder has been exposed a roll of gauze is carefully packed round the bladder, and the viscus itself is opened by a transverse incision. There is less bleeding when veins are cut across than when they are nicked, as may happen with the vertical incision, which is of course parallel to the course of the veins. Moreover, when the bladder is opened the peritoneum comes down into its usual position, and with a transverse incision through the bladder wall the incision can be lengthened if this be desired, much more safely than with a vertical cut. During the actual removal of the adenomata of the prostate, it is desirable that the patient should be deeply under the anæsthetic. Sir John Thomson-Walker has

spasmodic torticollis; the attacks have not recomm
since discontinuing the bromide.

Testing milk for purity

Purity has become an exact science at Bournville. Cadburys' analytical chemists are for ever making searching tests of ingredients that have in the first place been selected for their purity and goodness. Throughout that vast "factory in a garden" the most scrupulous cleanliness is observed. "Absolutely Pure" is Bournville's motto.

imagine that this operation can be as effective as the two-stage perineal excision with a permanent colostomy, which Lockhart-Mummery has described and performed with such success in this country. In discussing abdomino-perineal excision Prof. Hartmann expresses his belief that a terminal iliac colostomy is preferable to any attempt to bring down the pelvic colon to the anus, but it is evident that on the continent there is still a lingering tendency to perform operations which avoid colostomy. The results of 30 survivals from operation are given. Prof. Hartmann finds that recurrences as a rule show themselves within three years after operation, and working on this basis he estimates that his percentage of three-year cures is 56 per cent. (based on operation survivals). His actual operation mortality in recent years is not given. The operation of abdominal excision of a growth in the recto-sigmoidal region, with closure of the distal end, is described fully and well illustrated. This operation is very generally known as Hartmann's method, and the author's description of it, together with his personal results, deserves careful study. It is undoubtedly a valuable operation, and its soundness is based on careful anatomical researches.

This work contains sound and lucid surgical teaching given by a master of his art, and it will be studied with profit alike by specialist and general surgeon.

Modern Proctology.

By Marion C. Pruitt, M.D. Ga., F.R.C.S. Edin. London: Henry Kimpton. 1931. Pp. 404. 36*s*.

This book aims at giving a concise and comprehensive account of modern proctology. It is a curious mixture of good, bad, and indifferent. The good reflects the views of masters such as Cunningham, Ball, Tuttle, Bland-Sutton—nearly three pages are included on the subject of dermoids—Hill, Lockhart-Mummery, Rankin, and others. Mr. Pruitt's chapters in the early part of the book on constipation, fissure, abscesses, and hæmorrhoids are clear and adequate, and those on megacolon, stricture, and prolapse provide a sound summary of current opinion on these subjects.

It is in the later part of the book, where tumours are under discussion, that it becomes increasingly difficult to follow the author with interest or profit. Obsolete operations for cancer of the rectum are described and illustrated, such as perineal excision with preservation of the sphincters, Kraske's operation with the formation of a sacral anus, and vaginal excision of the rectum. The abdomino-anal excision is mentioned, but fortunately not described. Coffey's operation is reproduced, together with the usual illustrations. We must firmly oppose the author's contention that this operation is as effective as the one-stage operation of Mr. Ernest Miles. There are manifold reasons for believing that it is definitely inferior, and that some of the modifications, which involve section of the bowel and the trunk lymphatics, are not in accord with sound principles of radical cancer surgery. Throughout this section the only references to operation mortality are the figures published in the Ministry of Health Report in 1927, showing the operation mortality in relation to the height of the growth from the anus, and Coffey's report of his death-rate in 65 cases, which was published in Yeoman's text-book. As regards end-results, Rankin and Broders' table, showing the duration of life according to the malignancy grading, is reproduced, and there are figures relating to a series of 55 cases treated by lead injections; bu apart from this the author has no information to offer regarding prognosis after the different exci operations which he has described, nor has he referred to any of the recent papers published on the subject

In the discussion of resection of the pelvic colo we find a prominent row of Murphy's buttons depicted on p. 338, but there is no mention of the value of cæcostomy as an adjunct to end-to-end anastomo Paul's operation for extraperitoneal resection of the colon is described, but Rankin's method of obstructive resection and Devine's modification are not referred to. The description of the removal of a large adenoma from the rectum is so concise as to be almost without value, since the operation of posterior proctotomy is full of difficulty and many important details must be considered, while the importance of repeated and regular re-examination of such patient after operation is not stated.

Many of the illustrations have only historic interest, and others are so small and indistinct as t be of little value. The book leaves the impressio that the author's desire to present a complete encycl pædia on proctology led him to describe maj conditions of which he has little first-hand experienc This would be of less importance had his gleanin from the literature been made with discretion, a had full references to original papers been suppli

Surgical Pathology of the Genito-urina Organs.

By Arthur E.. Hertzler, M.D., Surgeon to Agnes Hertzler Memorial Hospital, Halste Kansas; Professor of Surgery, University Kansas. London: J. B. Lippincott Co. 1 Pp. 286. 21*s*.

While anatomy has always been recognised necessary foundation for surgical knowledge, i only during the last 50 years that a knowledg pathology has come to be considered of equal imp ance to a practical surgeon. Hertzler's work surgical pathology provides the operator with valu information which otherwise he would be comp to seek in books on general pathology which with every aspect of the subject. The third tre on regional pathology to appear under this ge heading is concerned with the genito-urinary or the other two being on the diseases of bones, an the skin, fasciæ, muscles, blood-vessels, and ly vessels. Seven other volumes are being prep and the complete series will thus consist of volumes. The fact that the volumes are not iso monographs enables the common factors of gro affecting the various systems to be made clear, and the editor is a general surgeon his wise judgme a safeguard against the evils of over-specialisa The ideal that the genito-urinary specialist sh have a sound general knowledge of the dis affecting the whole of the body while possessi special knowledge of those of the kidney, bla and genito-urinary tract is evidently held by Hertzler. He is himself a surgeon as well as a p logist, and it is therefore unnecessary to say th approaches his subject from the angle of pr rather than that of theory. His work is enriche 222 excellent illustrations, the great majorit which are from photographs of material obt from the Agnes Hertzler Memorial Hospital, Hals Kansas.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 6, 1932.

THE SPAHLINGER REMEDIES.

IN the winter of 1913–14 the late Dr. ARTHUR LATHAM collaborated with Mr. HENRY SPAHLINGER in the treatment of a number of cases of pulmonary tuberculosis at teaching hospitals in London and in Dr. Latham's private practice. The treatment was with vaccines and serums prepared by methods, not then made public, at Mr. Spahlinger's bacterio therapeutic institute at Carouge, near Geneva, where he had an experimental farm and a laboratory well equipped for serological and bacteriological research. The war intervened, during which the institute at Carouge was diverted to other purposes, and it was not until some ten years later that the Spahlinger treatment was heard of here. Mr. Spahlinger set out his claims for the cure of tuberculosis in his own words in our issue of Jan. 7th, 1922, and the British Red Cross voted a large sum of money to enable him to produce his remedies so that they might be tried in this country, while the Ministry of Health offered facilities for their experimental trial under scientific supervision so soon as supplies were available for the purpose. We ourselves appealed to Mr. Spahlinger to submit to the independent investigation of his remedy at one or other of the research institutes in this country, but, as our readers are aware, this appeal was unavailing, although we pursued for many months a policy of printing (without curtailment or comment) all cases, successful or unsuccessful, treated by this method, when submitted to us by medical men. In 1927 we published a review of the cases treated in 1913–14 at St. George's Hospital, with a clinical record setting out their subsequent history, and we took the opportunity again of appealing to Mr. Spahlinger to submit his remedies to the independent investigation which the Ministry of Health was still offering. The position varied but little until about a year ago, when the results were published of a test made at a Norfolk farm on the immunisation of calves against tubercle with a single dose of simplified bovine vaccine provided by Mr. Spahlinger; the committee of control included two veterinary surgeons who were satisfied that this vaccine conferred on calves an extremely strong resistance against tuberculosis. This vaccine was said to be prepared from dead germs and was not more nearly described.

The situation is now, however, changed, for, as will be seen from his letter to our correspondence columns, Mr. Spahlinger has made a statement of his method for the preparation of antigens, whether for the preventive vaccination of human beings or for cattle against tuberculosis. The details will be found set out word for word as he has communicated them to us on page 309 of our present issue. In this memorandum there are lacunæ which we hope will in due course be filled up. The salient points, however, may be enumerated as follows. In the preparation of the bovine vaccine primary cultures are made direct from slaughter-house material without preliminary passage through animals, and, presumably, without treatment with acid or alkali to destroy any stray secondary organisms, such as is the usual practice nowadays. The media on which the primary cultures are made consist of a mixture of heated and unheated "defibrinated blood, serum, organ or tissue extract" from a bovine source. The ingenious method of applying the unheated portion to the surface of the coagulated medium is an elaboration of a method of applying fresh blood to the surface of an agar slope devised years ago for cultivating the pneumococcus. Koch used coagulated serum in his early experiments on the cultivation of the tubercle bacillus, but nowadays we believe most bacteriologists have relinquished serum in favour of egg media on which primary implantations appear to do better. Tissue extract has occasionally been tried but has been very little used by tuberculosis workers. Mr. Spahlinger does not state what tissues or organs he uses and gives no details as to his methods of extraction, filtration, &c. The first subcultures are preferably made on liquid media of the same substances. Here again no details are given as to the method of preparing the tissue extracts or as to their strength, but later in the memorandum it is stated that in cultivating the human strain small amounts of saline, glycerin, or glucose may be added. As a rule in most laboratories we believe first subcultures are made on solid media and continued thereon till the cultures grow readily. In making the vaccine emulsion from the subcultures, Mr. Spahlinger tells us that the "tubercle micro-organisms are collected and made into an emulsion in a sterile manner, in the absence of oxygen, with distilled water or normal saline solution." No details are given as to the method of removal of oxygen, but we presume the emulsion is treated in vacuo. Also—and this is an important omission—Mr. Spahlinger does not state the method of estimating the strength of the bacterial emulsion he employs. After distribution of his emulsion into ampoules the organisms contained therein are left to die a natural death by the efflux of time—which takes a year or even longer. This, we believe, is a new departure. Many physical and chemical methods have been

THEELIN

The Ovarian Follicular Hormone in Crystalline Form

IN AMPOULES & VAGINAL SUPPOSITORIES

THEELIN (θηλυ = female sex) is the name given to the ovarian follicular hormone first isolated in crystalline form by Dr. E. A. Doisy, Professor of Biochemistry at the University of St. Louis.

¶ The potency of Theelin is indicated by the fact that one milligramme is equivalent to at least 3,000 Doisy rat-units.

¶ Theelin is indicated in the treatment of functional amenorrhœa, in the subjective disturbance of either artificial or natural menopause, delayed puberty, and in fact, all those conditions where less purified ovarian extracts have been used. It has the great advantage that it is free from certain side reactions which may have been caused by the impurities present in varying amounts in the crude ovarian and follicular products.

¶ Theelin is usually administered in solution, by intramuscular or subcutaneous injection, in doses of from 50 to 100 rat-units. The same physiological effect is produced when Theelin is applied intravaginally by means of suppositories, although somewhat larger doses may be required to produce the same results.

¶ Theelin is manufactured by Parke, Davis & Co., under licence from the University of St. Louis. Each batch of the product is tested and approved at the Biochemical Laboratory of that University before being released for sale.

Issued in solution, for intramuscular injection, in packages of six 1 c.c. ampoules, each ampoule containing 50 Doisy rat-units; also as vaginal suppositories in boxes of six, each containing 50 Doisy rat-units. Further particulars will be sent on request.

nism. The idea of cause and effect being solubly and invariably related in exactly the me way has grown weaker; it seems not unlikely at their connexion is one of probability rather an certainty, as Prof. KARL PEARSON suggested ng ago in "The Grammar of Science." When e deal with the phenomena of chemistry and ysics where in general innumerable units are ncerned, the exceptional result is overwhelmed y the average and is imperceptible. In biology, here we can observe isolated units, we can see dividual results and it becomes apparent that he same cause is not always followed by exactly he same effect. Atoms might well have the same egree of free-will if we could study them by hemselves. Prof. CLARK therefore finds nothing in xperimental science which is antagonistic to or ncompatible with the appreciation of spiritual alues. A further testimony to the same effect ill be found in a very striking document by Sir DANIEL HALL, the distinguished agriculturist, printed in the December number of the *Nineteenth Century and After*. Telling us the tale of his personal pilgrimage, he confirms the general experience that the mind instinctively demands some scheme which will reconcile the spiritual and mechanical facts of observation. It was in Berkeley's argument for the non-existence of material things that he found an escape from the difficulties of a mechanical conception of the universe and from the dilemma of free-will and determinism. If the ultimate reality is mind, the laws of the universe which we formulate are no more than modes of thought and they may very well appear to be inconsistent among themselves because our minds are only fragments of the whole mind: they are aspects of reality, not reality itself. Hence, too, our observations of the spiritual side of life are just as real as our records of the material world. Disinterestedness is simply an observed fact of human conduct and righteousness is just as much a human quality as intelligence. Both are fitful in their operations, irregular in their distribution, and unequal in their intensity, but their existence is a fact of observation as valid as any mechanical measurement; no account of the universe can neglect them without being obviously incomplete.

◆

THE TREATMENT OF TOXIC DIPHTHERIA.

DIPHTHERIA is a preventable disease. Where, as in New York City,[1] active immunisation is carried out upon an adequate scale, morbidity and mortality have declined notably. In this country active immunisation is at last making headway, but so far the numbers of children protected are too small to produce any appreciable effect upon prevalence. Case-mortality, on the other hand, has been declining for a generation. Without doubt, diphtheria antitoxin has been the main factor, but not the only factor, in bringing about the great fall in the fatality-rate. The fatality-rates of other common acute infectious diseases, for which no specific measures of treatment are available, have also steadily declined within the same period. Discussion of the causes of this general decline is beyond our present purpose. Case-mortality from diphtheria in this country now ranges from about 4 to 6 per cent., varying somewhat in different years and in different towns. Fatalities in diphtheria are almost entirely accounted for by the laryngeal form and by the toxic faucial case. Whatever the reasons, there can be no question that the proportion of severely toxic cases of the disease varies in different epidemics in the same city and in different cities at the same time. Berlin a few years ago experienced an epidemic of diphtheria during which cases of toxic type occurred in alarming numbers. In Hamburg, on the other hand, at the same period, diphtheria was neither unduly prevalent nor exceptionally severe.

Cases of faucial diphtheria have been encountered in whose treatment diphtheria antitoxin, although administered early and in adequate dosage, is stated to have been of no avail. Toxæmia from the first was apparently overwhelming. But such cases must be very exceptional. Very many more cases, unfortunately, are daily met with where prompt injection of a moderate dose of antitoxin might have averted that tragedy of infectious diseases hospitals—the case of toxic diphtheria which comes under treatment too late. All admit the necessity for antitoxin in the treatment of diphtheria and the prime importance of its early administration. Most, perhaps, are now agreed that in the severe case of diphtheria a portion, at any rate, of the dose should be injected intravenously. As to the size of the dose, the number of units, there are many differences of opinion. V. BIE, of Copenhagen, who claims that his low case-mortality is due to the use of very large doses,[2] has injected an aggregate dose of 500,000 antitoxic units; W. H. PARK, of New York, a strong upholder of the intravenous route, would not exceed at most 50,000 units; E. W. GOODALL's upward limit is 30,000 units. In some late cases of toxic diphtheria no dose of antitoxin of whatever magnitude is of any avail. Antitoxin can only adsorb circulating toxin and possibly toxin but loosely fixed in the tissues. It cannot repair structural damage.

On another page appears a paper by Drs. BENN, HUGHES, and ALSTEAD upon the treatment of toxic diphtheria by combined antitoxin and dextrose-insulin therapy. As they point out, F. F. SCHWENTKER and W. W. NOEL, in the course of a comprehensive reinvestigation of the causes of circulatory failure in diphtheria, have produced evidence, from their own observations and those of others, that the toxin of diphtheria causes profound changes in carbohydrate metabolism. In the severe case there is at first a rise in the blood-sugar which is due to an increased glycogenolysis, glycogen disappears from the liver and, most significantly, from the bundle of His employed in the past for this purpose, but we do not recollect having read of this. Each batch of vaccine is tested before use to be quite sure that no living tubercle bacilli remain. In the case of vaccine for use in man there are added to the bovine vaccine (*a*) a vaccine of bovine bacilli grown on media from human sources, (*b*) of human bacilli grown on media from human sources, the media being prepared from "defibrinated blood, serum, ascitic or pleural fluids" which must be taken from "tuberculous-free bodies." Details of preparation are not given. The question of dosage of the vaccine is not dealt with in the memorandum, but it is stated that the relative proportions of the three types of culture used in the vaccine for man "vary according to the nature of the particular type of the tuberculous disease."

---

[1] Report of Commissioner of Health for New York City, 1931.

[2] See THE LANCET, 1928, ii., 21.

Now that Mr. Spahlinger has given to the world this much of his methods we hope that he will be persuaded to give full working details and especially to fill some of the lacunæ we have pointed out. The formula has been released, we are told, through the generosity of a small group of public-spirited people who are animated by humanitarian motives but wish to avoid the possibility of improper exploitation of the remedies. The Therapeutic Substances Act should be a sufficient guarantee against their fear of cheap and hasty manufacture. Mr. Spahlinger may safely join the freemasonry of bacteriologists who share their knowledge for the benefit of medicine and mankind.

◆

THE PHILOSOPHY OF BIOLOGISTS.

THE aim of scientific workers, in so far as they have had any definite formulated aim at all, has always been to construct a logical coherent systematic explanation of the world as they perceive it, in which effects follow causes with such implacable regularity that the one may with certainty be deduced from the other. Since each effect must in its turn be a cause, such a world *obviously consists of a predetermined procession*, and it is very difficult to harmonise it with the belief innate in every human being that he has at least some control over what he does and that what he does makes a difference. We doubt whether the majority of those who are interested in natural knowledge ever pose this dilemma to themselves. Absorbed in the problem of the moment, they do not spend much time in reflecting on their ultimate aims, nor does it occur to them that the more they expose the predestined chain of events at which they happen to be working, the more they undermine the position of the free-will on which, as they would doubtless say, their progress depends. But if in moments of being by themselves the matter does happen to occur to their consideration, they must needs recognise that the dilemma is a real one of which there is no ready solution. Prof. A. J. CLARK, of Edinburgh, made it the text of a discourse he gave last autumn to the Quaker Medical Society which is published in the current number of the *Friends' Quarterly Examiner*, and he gives us an interesting survey of the problem of vitalism versus mechanism as it appears to one who has spent his scientific life in the rigorous examination of the properties of living tissues by the analytical methods of experimental physiology.

On the whole, Prof. CLARK is entirely dissatisfied with the attempts which have been made to explain life in terms of chemistry and physics. He freely admits that very substantial progress has been achieved in working out the physico-chemical basis of many of the mechanisms which are found operating in live animals, though even here he points out that some of these explanations fail t account for the phenomena while others have been based on conceptions of the inorganic world whic have turned out to be fallacious. But the essenti difficulty is that the discovery of living mechanism has not brought us much nearer the discovery life, and in this criticism he reaches the point which mechanist and vitalist part company. Wh an animal does is, according to the mechani determined by the available mechanisms; to vitalist, these mechanisms are no more than t means by which the animal reaches its objec In homely simile, the mechanist would hope explain why Jones goes from Piccadilly Circus the Bank by a quantitative study of the vari means of transport which are available; these of quite subsidiary interest to the vitalist who in them nothing but a series of alternative mech isms which do not help us at all to underst why Jones starts in one place and ends up in other. Life in short is something more than the sum of the activities into which organisms can be dissected, and he quotes SMUTS'S summary with approval: "the nature of living things is determined, not by the nature of their parts, but by the nature or principle of their organisation"; mechanism does nothing to explain the correlation and coördination which are so characteristic of organisms. Prof. CLARK also objects to determinism because it denies all significance to consciousness and, as he says, we are more certain of *the* existence of *consciousness than* we are of any other fact. Evidently he has no sympathy with those who would solve these troubles by cutting human experience into two halves which may roughly be called the material and the spiritual; man is essentially a religious animal and no explanation of life is satisfying which does not take this into account. The mechanistic method of approach should be given up and the biologist should concentrate on discovering not the features which living organisms share with dead matter, but the features in which the two differ. Only in this way, he says, shall we obtain a just view of what the properties of life really are.

It may be suggested in commentary that the difficulties indicated by Prof. CLARK are perhaps less than they used to be. Modern physics has gone some way to assimilate its conceptions to those of biology and the distinction between liv and dead has *become* less definite; it seems possible, indeed, that *everything* from the electro to man might go into a series graded quantitatively rather than qualitatively. So too with deter

ANNOTATIONS

THE HEREDITY OF DIABETES.

HEREDITY has been recognised as an ætiological tor in diabetes since the sixteenth century, but I. S. Wright reminds us.[1] H. A. H. Howard d P. J. Cammidge were the first to show at a high blood-sugar might be transmitted in ice according to Mendelian law. They found at if certain mice having a high fasting blood-gar were mated they produced offspring having e same high blood-sugar; if, on the other ınd, they were crossed with mice having normal ood-sugars all the progeny were normal in this spect. When, however, these seemingly normal ıice were crossed with mice having a high blood-sugar ıe results followed the Mendelian law and the umber of offspring which had high blood-sugar nd those which were apparently normal or hybrid arriers was equal. If the hybrid carriers were ıated with each other the progeny had high blood-ugar in the proportion of one in three. It could be oncluded from these experiments that high blood-ugar was a recessive characteristic, and that the pparently normal hybrid carriers were capable of ransmitting it to their offspring according to Mendelian law. Cammidge in a study of English families found that the same laws were followed. When the disease was transmitted as a dominant characteristic the course was found to be mild; when the characteristic was recessive, the course was usually grave from the onset.

Wright himself describes a series of families in which the hereditary influence of diabetes is very clear. He gives charts of nine families, in three of which both the parents were known to have diabetes. One of the latter group is especially remarkable, for of 30 people belonging to two successive generations 18 were affected with diabetes. In the third generation none of the six children of a diabetic father has developed diabetes but three of them are bleeders. Wright thinks that there are two factors which tend to produce diabetes—namely, a hereditary factor and an acquired factor such as infection or obesity. In any given case either may preponderate, but if both are large the disease seems to be inevitable, whereas if both are small or one is absent it may never appear at all. In this series, as in Cammidge's, when the characteristic was dominant the disease tended to be mild, and there is evidence to show that diabetes innocens (renal or orthoglycæmic glycosuria) is transmitted in a somewhat similar manner. Urban Hjärne[2] has investigated a remarkable family many members of which had glycosuria. He was able to study seven generations, but found no evidence of any abnormality in the first three. In the fourth, which comprised 18 persons, only one had glycosuria, and this did not run the course of true diabetes mellitus. In the third generation there had been a marriage between first cousins, and in the fourth generation one of the children of this marriage had again married a cousin. The members of the next three generations therefore could be divided into three groups according to whether they sprang from two, one, or no first-cousin marriages. Of the first group of 41 persons, 30 were examined and 16 were found to have renal glycosuria as shown by sugar-tolerance tests. In the group springing from one first-cousin marriage, 77 out of 108 were examined and 14 had either a renal glycosuria or a glycosuria without any symptoms, and two had true diabetes mellitus. In the group in which there had been no intermarriage, 72 out of 102 were examined, and ten of these had renal glycosuria and two had true diabetes. It will be remembered also that Parkes Weber[3] has lately described a family in which the mother had had glycosuria without symptoms for 44 years. Of her five children, four had glycosuria without hyperglycæmia, while the fifth, who had a different father, was normal.

Now that insulin has completely altered the outlook for younger diabetics, the ætiological importance of heredity ceases to be of merely academic interest. Requests for advice from diabetics as to whether they may marry become more frequent every year. The best advice can only be given from a clearer knowledge of the importance of the hereditary factor.

THE LEAGUE OF NATIONS AND THE OPIUM TRAFFIC.

THE Council of the League of Nations, now in session at Geneva, will have before it for consideration some of the recent developments directed to the better control of international traffic in narcotic drugs. The convention drawn up in July, 1931, dealing with limitation of the manufacture and distribution of morphine and cocaine and their derivatives, though signed by more than 40 governments, cannot be effectuated until ratified or acceded to by 25 states, members of the League or non-members. Since great importance is attached to the provisions of this convention, and the new machinery which it invokes with a view to checking the appalling amount of illicit traffic in narcotic drugs which has been reported to the League, it is presumed that pressure will be brought to bear upon the signatory Powers to proceed to early ratification. It will be remembered that the assembly of the League last autumn regarded the new convention as but the first step towards the limitation of the production of the raw materials of these pharmaceutical preparations. The original opium convention signed at The Hague in 1912 sought also to limit and control the production of raw opium, and to bring about the gradual and effective suppression of smoking of "prepared" opium. The Geneva convention of 1925, which purported to "complete and strengthen" the provisions of the earlier treaty, nevertheless postponed the period by which the contemplated suppression of opium smoking should be achieved. A commission of inquiry appointed by the council of the League in 1929 visited the Far East to report upon the measures which had been taken, or should be taken, to fulfil the treaty obligations in regard to opium smoking. It presented most elaborate reports on the above question, three volumes of which have been published.[4] A conference convened by the council of the League was held at Bangkok in November, 1931, to consider the situation in regard to opium smoking as disclosed by the reports of the commission. It was attended by representatives of Great Britain, France, India (Burma), Japan, Netherlands, Portugal.

and hyperglycæmia may be succeeded, as toxæmia increases, by hypoglycæmia. Finally, owing to the failure of insulin-production by the pancreas and of other normal sources of supply, as the result of damage to the tissues generally, the blood-sugar again rises with the production of hyperglycæmia. Various observers have reported that the blood-sugar curve in toxic diphtheria is of diabetic type, and Dr. BENN and his colleagues are able to show that the greater the degree of lag exhibited by the curve the worse the prognosis of the case. They detail two series of cases of toxic diphtheria which although not contemporaneous are of comparable clinical severity. The patients in both series received, it will be observed, large doses of antitoxin, usually by both intramuscular and intravenous routes. The average total unitage in both series is fairly comparable. (As to whether a more moderate unitage in both series might have sufficed we express no opinion.) In Series A besides the large doses of antitoxin the patients received dextrose intravenously and subsequently glucose by mouth, and where the nature of the blood-sugar curve appeared to indicate its necessity, insulin intramuscularly. A consideration of the case-mortality and the paresis rate in the two series shows important differences in favour of the dextrose-insulin series. Whereas in that series the case-mortality of 89 consecutive cases of toxic type was 22·5 per cent., in the control series of 131 similar cases treated with antitoxin alone the case-mortality was 35·9 per cent. It can be shown that this difference in the case-mortality in the two series amounts to three times the probable error and therefore must be regarded as significant. The difference is not due to chance. As a matter of fact, the real difference is slightly greater than the authors show. This is due to variations in the age-distribution of the cases in the two series which are not in this respect strictly comparable as the authors state. In the experimental Series A, 65 per cent. of the patients were under 10 years of age; in the control Series B 57 per cent. only. The case-mortality amongst this age-group was 24 per cent. in the experimental series and 45 per cent. in the control series. The difference in the recovery—with paresis rate in the two series is noteworthy; it is 57·3 per cent. in the experimental series and 44·2 per cent. in the control series. It is a fair inference that more patients in the dextrose-insulin series survived to experience pareses in the later stages of the disease.

The administration of glucose in the toxæmia of diphtheria, as in toxæmia due to other infections, is not new. Glucose is now given orally to cases of diphtheria in many fever hospitals, and its use as an adjunct to antitoxin should become general. F. J. HECTOR [3] first suggested the injection of insulin in diphtheria. Provided, and only provided, that facilities are at hand for repeated estimations of the blood-sugar, its use in the type of case described by Dr. BENN may turn the scale. Uncontrolled injections of insulin in diphtheria are dangerous and should never be attempted. There is too great a risk of hypoglycæmia which may be mistaken for a cerebral complication of the disease.

◆

MEMORIAL TO SIR ANDREW BALFOUR

Sir James Crichton-Browne and a score of others whose names are outstanding in scientific endeavour are signatories to a letter appealing for funds to keep green the memory of Sir Andrew Balfour in the London School of Hygiene and Tropical Medicine. The monument itself is to be simple and inexpensive, appropriate to a man whose influence upon his fellows was so largely due to simplicity of character and sterling honesty of purpose. The school itself is his true memorial, for, as the Prince of Wales said when he opened it, it is a sign that post-graduate education in medicine is about to come into its own; and Balfour supervised every detail in the conception of the school and the structure of the building, keeping in view all the while that it was first and all the time a workshop for the well-being of the Empire. The greater part of the funds will be allotted to helping students, preferably from overseas, to pursue courses of study at the school, and the cosmopolitan preference is again agreeable to the memory of one whose first piece of work was to cleanse the Augean stables of the Khalifate and transform them into the modern well-planned city of Khartoum. During the war here and there, first at Salonica and Egypt, then in Mesopotamia, in East Africa and Uganda, Balfour served as president of a medical advisory committee organising sanitary reforms which have lasted on into peaceful times. His earlier journeys took him to the West Indies and South America, his later ones to Mauritius and Bermuda. There is a fitness in associating his memory with the opportunity for students from every part of the Commonwealth to study the principles of healthy living at the Rockefeller house in Gower-street.

DAWSON WILLIAMS MEMORIAL PRIZE.—The Dawson Williams Memorial Fund was established by a voluntary subscription amongst the friends and admirers of the late Editor of the *British Medical Journal* in 1928. The administration of the fund was placed in the hands of a body of trustees composed of the following:—The presidents (for the time being) of the Royal College of Physicians of London, the Royal College of Surgeons of England, the British Medical Association, the Royal Society of Medicine, and the Section for Disease in Children of the Royal Society of Medicine; and the Editor of the *British Medical Journal*. The object of the fund is the award of a prize, every two years or at longer intervals at the discretion of the trustees, in recognition of work done in connexion with pædiatrics. The first award was made in 1930 to Dr F. J. Poynton, for his work on behalf of rheumatic children particularly with regard to the establishment of specia "rheumatic centres"; and the trustees have decided t make the second award this year to Sir Robert Jones fo his work in connexion with the pædiatric side of orthopædics. With the consent of the Council of the Britis Medical Association the prize will be presented by th President of the Association on the occasion of his presdential address on Tuesday, July 20th.

r-car by a boy unfitted to handle it. He wished a method of restricting liberty existed half-way veen probation and imprisonment. Finally, on her matter, he made the pertinent inquiry ther the State, now that it assumed responsibility giving every life a chance, might not have some in the question whether in a given case a life uld ever exist. It was significant that every er speaker advocated some form of restriction liberty; the consensus of opinion was that the ion was suffering, like Lucio's friend in Measure Measure, from "Liberty; too much liberty." erty demands a sense of responsibility, and only se prepared to take responsibility can claim it.

TUMOURS OF THE BILE-DUCTS.

During the 20 years 1910–29 53 tumours of the e-ducts were observed at the Mayo Clinic, all cept four of them being malignant. Dr. James M. rshall has collected and analysed these cases in a ent paper.[1] Benign tumours of the extra-hepatic cts, of which H. D. Rolleston and J. W. McNee und only ten cases on record in 1929, are usually pillomatous, fibromatous, or adenofibromatous. vo of Marshall's cases were adenofibromata, one a pilloma and one a congenital cyst of the cystic duct. he 49 malignant tumours were all examples of imary carcinoma. Operation was performed in 5 cases, and in four the condition was found at topsy. Three-fourths of the patients were over 0 years of age, the youngest being aged 23 years; 1 were males, and 18 females. Gall-stones were resent in the gall-bladder or ducts or both in 21 ases (43 per cent.). The commonest sites of the umours were the lower end of the common bile-duct nd the ampulla of Vater. The usual clinical picture vas that of obstructive jaundice, which was present n 44 cases, and varied in degree from slight to extreme. Marked loss of weight was seen in 45 patients and was he most striking manifestation after jaundice. Pain was absent in 15 cases throughout the entire course of the illness, and therefore the presence or absence of pain appears to be of little, if any, diagnostic significance. Pruritus was a prominent symptom in 25 cases, and in several it was the chief complaint. Spontaneous hæmorrhages occurred in 16 cases. Of the 45 patients on whom operation was performed for carcinoma 19 (42·2 per cent.) died within 30 days, 26 survived for an average period of 17·3 months; of these three were still living, respectively, seven months, 20 months, and 34 months after the operation, and in six patients the results were unknown. The high operative mortality is attributed to the tendency to hæmorrhage and technical difficulties of operations on the biliary tract.

THE LIVER AND HÆMOGLOBIN.

It used to be supposed that it was the business of the liver to make bile-pigments out of the remains of red corpuscles. The hæmatoidin crystals in old hæmorrhages showed that the manufacture of bilirubin was not the sole prerogative of the liver, but it has been left to recent experimental research to show that the tissues of the body generally have this capacity. The point which remains in doubt is whether the liver can do it at all; the facts are consistent with the interpretation that its only share in the process is to pick up bile-pigment from the blood and pass it into the bile-ducts. But it has still been generally believed that the liver plays an important part in removing free hæmoglobin from the circulation when, for any reason, red cells have been broken up in the blood, and it is something of a surprise to learn from some recent work by Profs. R. Muir and J. S. Young[1] that this too is in doubt. When a single large dose of dissolved hæmoglobin is injected intravenously, none is excreted in the bile nor do the liver cells show any evidence of hæmoglobin or of an iron-containing pigment. The cells of the convoluted tubules of the kidney, on the other hand, gave a diffuse reaction for iron which, after two or three days, took on a granular form. The spleen was found normal in all respects. When smaller doses were given over a longer period, a marked siderosis of the convoluted tubules of the kidneys was produced. It is known that hæmoglobin free in the blood plasma passes through the glomeruli and it is, no doubt, by reabsorption that it finds its way into the cells of the tubules. This is apparently why a certain amount of hæmoglobinæmia may exist without any hæmoglobinuria. The liver, on the other hand, showed relatively slight or hardly any accumulation of iron, either in the liver cells themselves or in the Kupffer cells. And the authors are disinclined to believe that such increase in the liver as they found really represents any active interest in hæmoglobin. Both spleen and bone-marrow showed more than the normal quantum of hæmosiderin and presumably take their parts in disposing of a hæmoglobinæmia.

ANÆMIA WITH DYSPHAGIA.

The recrudescence of interest in secondary anæmia during the last few years has brought into prominence what has been called the Plummer-Vinson syndrome. In 1922 Vinson associated the peculiar dysphagia, first described eight years previously by Plummer, with a severe secondary anæmia, and we now have records of many cases belonging to this group, a summary being published in 1928 by J. A. Munro Cameron.[2] The main points in the syndrome are that the mucosa of the mouth, pharynx, and œsophagus shows inflammatory changes producing dysphagia, and that the patients exhibit severe anæmia of secondary type. It has been claimed that relief of the dysphagia, which can sometimes be brought about by the mere passage of a tube, will so improve the food intake that the anæmia disappears. Dr. George Graham and Dr. R. S. Johnson[3] now report a series of cases in which they have observed that besides the syndrome as described, there is a definite increase in the fragility of the red blood corpuscles. They call attention to the colour of the skin, which is of a brownish-yellow tint rather than the so-called lemon-yellow of pernicious anæmia. Achlorhydria was present in all their cases, but the histamine test was not performed, and therefore they are unable to say whether the achlorhydria was absolute. On careful test of the fragility of the red corpuscles they found that usually hæmolysis began in concentrations of normal saline higher than 0·50, and was always complete at 0·40. The distinction from acholuric jaundice was confirmed, apart from the dysphagia, by the absence of excess of bilirubin from the blood-serum, whilst the achlorhydria was further evidence. Graham and Johnson are unable to confirm the reported cure of such cases by the simple administration of a full ordinary diet, but found that the anæmia rapidly improved when and Siam, while an observer was sent by the United States of America.

The conference is reported to have adopted a new agreement and final Act dealing with the prohibition of the retail of smoking opium through persons receiving commissions; the definition of minors to whom smoking is forbidden; penalties for inciting minors to smoke; and prohibiting the sale of prepared opium otherwise than for cash. The conference does not appear to have fixed a date from which the 15 years allowed by the Geneva convention for the gradual suppression of opium smoking was to commence. The representative of the United States demurred to the implied double standard whereby governments with Far Eastern possessions sanctioned opium smoking therein while proscribing it absolutely in the home countries. He likewise opposed a government monopoly system which was favoured by other members of the conference, and indeed he contended "that there is but one real method by which to suppress the evil of opium smoking, and that is complete statutory prohibition of the importation, manufacture, sale, possession, or use of prepared opium."

WHAT PROMOTES TUBERCULOSIS MOST?

IT is pretty safe to say that if a score or two of authorities on tuberculosis were asked this question, they would not agree over the answer. In other words, we are still to a certain extent in the dark over the most important question that can be raised in this field. Dr. O. Scheel,[1] chief of a medical service of the Ullevaal communal hospital of Oslo, has lately set out his view that the standard of living is far and away the most important factor in tuberculosis, and that the age at which infection occurs, the intensity of infection, recurrent super-infections, sanatorium treatment, and various other factors play a subsidiary, and perhaps even a negligible rôle. None of the elements of this thesis is new, and at the present time few would deny the importance of the general standard of living in relation to immunity to tuberculosis. The mass experiment in Germany during the late war is in this connexion unanswerable. But Dr. Scheel is greatly daring in this: that he brushes aside as unimportant all the other factors which are supposed to play a part in tuberculosis, and which have determined the expenditure of enormous sums of money during the past half century. Long before the discovery of the tubercle bacillus and the campaign against tuberculosis as an infectious disease was started, the mortality from tuberculosis as well as the general mortality had begun to decline. And while it is thus impossible to correlate the decline in tuberculosis exclusively with the modern campaign against it as an infectious disease, it is possible to establish an intimate association with this decline and the rise in the standard of living for which modern industry is responsible. It has been calculated that during the four centuries before 1880, the stature of the average Norwegian increased by 4 cm. Between 1880 and 1926 it increased by 2·5 to 3 cm., if measurements of recruits during this latter period can be applied to the whole population. Similar increases of stature have been observed in several other countries. Measurements in Norway of young adults belonging to different social classes have shown that the stature of the average man rises with his social status—another proof that stature is determined, to a certain extent, by the standard of living. So far Dr. Scheel is on fairly safe ground H becomes more interesting as he leaves this ground t skate on thin ice by challenging Newsholme's vi in 1906 that the principal cause of the decline tuberculosis is the campaign waged against it as infectious disease. In 1928 there were about 30 infectious cases of tuberculosis in Norway, with onl 5300 beds set aside for them. In other word Norway cannot expect to isolate more than so 18 per cent. of her infectious tuberculous ca Complete isolation of all her infectious cases w in Dr. Scheel's opinion, never be feasible. Parti isolation merely has the effect of deferring the ag of infection in a certain proportion of the populatio nearly all of which, however, is tuberculin posit at the age of 30. Does putting off the evil da from infancy or childhood to adolescence or ear adult life, matter much? As far as girls are co cerned, Dr. Scheel greatly doubts if it is better be infected between the ages of 15 and 20 than school age. He is also sceptical about the importan of the degree of infection, of super-infections, and sanatoriums either as isolation or as therapeu establishments.

THE LIBERTY OF THE SUBJECT.

THE Medico-Legal Society's discussion last w like most other discussions on the Liberty of Subject, covered a very wide field. Dr. L Weatherly gave his views on the regulations u the Defence of the Realm Act, abortion, the position of alcoholics, and the segregation of m defectives. As a veteran psychiatrist, he de a large portion of his address to the working o Mental Treatment Act and criticised the Boa Control for what he described as a "bureau attitude." He also blamed many large m palities for not establishing juvenile cour connexion with their police-courts, and fo administering the Probation of Offenders Act full a measure as it could be administered. accusation drew from Mr. Claud Mullins, the known writer on law reform, an excellent defe magistrates in general. Mr. Mullins, him magistrate, agreed completely with Dr. We on the stupidity of many of the minor regu which had to be enforced in the police-court. I that he wished that legislators, when passing restrictive laws, would sometimes consider the qu not only whether a certain state of affair desirable but whether the laws could be enf and whether the effort to enforce them was while. On the previous day, he said, he had an hour of his public time discussing whet black-currant pastille was properly so-called w contained no currant. His deliberations had complicated by the fact that two learned a had sent him two independent and com different reports on the composition of the p in question. The number of regulations wh was expected to enforce was, he said, amazin they all meant a certain amount of interferenc liberty and considerable expense to the On the subject of probation he uttered a needed reminder that the probation of offende capable of serious misuse. It had, he said noised abroad that the effect of the Act was t every dog to have one bite—a dangerous do It was constantly reported to him by policem missionaries that young offenders said, "O Beak will bind me over; it's a first offence," when the offence was that of driving away an uni

STUDY OF THE B C G STRAIN OF TUBERCLE BACILLUS.

TH AN ACCOUNT OF TWO IMMUNITY EXPERIMENTS AND A PRELIMINARY REPORT ON THE CULTIVATION OF TUBERCLE BACILLI ON BILE MEDIA.

By A. Stanley Griffith, M.D. Vict.,
Ph.D. Camb.,

MBER OF THE SCIENTIFIC STAFF, MEDICAL RESEARCH COUNCIL.

(From the Field Laboratories, University of Cambridge.)

The organism known as B C G (Bacillo Calmette-uérin) is stated to be lineally descended from ovine tubercle bacilli isolated by Nocard, in 1901, om the milk of a tuberculous cow. Beginning in e year 1907 the strain was subcultured at intervals f from 14 to 25 days upon potato saturated with ·0 per cent. glycerin ox-bile. During the course of he cultivation on this bile medium the organism, riginally of normal "bovine" virulence, became less and less tuberculigenic" and eventually, fter 230 successive subcultures in 13 years, was ound to have lost the power of producing progressive uberculosis in all the domesticated species of animals nd in the highly susceptible monkey.

My investigations of the strain, which have been made over a period of several years, include virulence tests and immunity experiments on various species of animals. In this paper I am reporting the results of the virulence tests and observations on the cultural characteristics.

Two strains of B C G have been used in the investigation. They were both kindly sent to me by Prof. A. Calmette, one in 1921, the other in 1927. The strains proved identical, but the former has been used almost to the exclusion of the latter for the passage and immunity experiments.

My reason for obtaining the strain in the first instance was for the purpose of ascertaining whether or not it could be identified by serological or other tests with any of the well-defined types of tubercle bacilli. Several strains of tubercle bacilli labelled either human or bovine which I had obtained from other laboratories proved on investigation (1925)[1] to have characteristics appertaining to the avian type of tubercle bacillus, and the pathogenic history of B C G (see Calmette[2]) suggested to me the possibility that this strain also might belong to the avian type. I refer particularly to the statement that the strain had lost virulence for the guinea-pig after only 15 subcultures on bile media while retaining it for the rabbit (and the horse) after four years subculture; non-pathogenicity for the guinea-pig with some virulence for the rabbit are features which distinguish the avian from the mammalian types of tubercle bacilli. Also the effects produced in the guinea-pig (acute tuberculosis after intraperitoneal and non-progressive tuberculosis after subcutaneous inoculation) and in the calf (typho-bacillosis without follicular lesions) by the early bile subcultures resembled more those of the avian bacillus than of mammalian bacilli. I may say at once that neither of the two strains exhibit now any of the characteristics of the standard avian tubercle bacillus.

The 1921 strain was subcultured by me on glycerin bile potato for about 18 months (16 transferences), and has since been maintained on plain egg or glycerin egg without bile.

Cultural Characteristics.

The organism has been recovered in culture from many of the several different species of animals inoculated with it. In primary culture on egg and glycerin egg the colonies become visible to the naked eye in the third week and under magnification are seen to be rounded, shiny, and somewhat translucent. On egg the colonies when numerous remain small and fairly uniform; a developed colony has a dome-shaped moist ivory white waxy centre with smooth or granular surface and a thin almost transparent broad crenated margin; on glycerin egg the colonies grow larger than on egg and when numerous coalesce to form a thick, opaque, white, irregular warty layer. When sparsely scattered the colonies grow large and may vary very much in appearance. Three chief forms of large colony have been distinguished:

1. *Flat spreading grey or greyish-white colonies with a* granular surface and a heaped-up warty centre; sometimes there is a coarse warty centre with a narrow margin; the width of the flat marginal part apparently depends upon the degree *of moisture of the medium.*
2. Colonies with a hollow or depressed centre; small varieties resemble a bead, medium-sized varieties are umbilicated, radially divided into segments and resemble a rosette; still *larger varieties are crateriform, often very irregular and* heaped-up, becoming with age studded with small pearly secondary colonies.
3. Convoluted heaped-up colonies with a broad sloping *greyish-white granular margin; the central part may* be conical with smooth radial folds deeply indented or elaborately coiled, and often takes on a reddish colour. This is the "R" form of Petroff[3] and is seen most commonly on glycerin egg. Subcultures of these colonial variants showed no distinguishing features and in virulence tests behaved like the parent strain.

On egg subcultures showed white crumbly masses. On glycerin egg growth was more luxuriant, slightly creamy, nodular, sometimes wrinkled. On bovine serum growth was good but not pigmented. On glycerin agar cultures were luxuriant, creamy, and composed of nodules resembling worm-casts. On glycerin potato the strain also grew luxuriantly, producing creamy warty or wrinkled layers; blue litmus potato was sometimes turned pink. On an asparagin medium and on glycerin broth the bacillus formed a thick whitish pellicle.

The serological reactions of the strain are those of mammalian tubercle bacilli. The bacilli are acid-fast and Gram-fast. Old cultures show vacuolated and palely stained longish forms with dark granules, but no definite branched forms have been seen.

Experiments on Guinea-pigs.

VIRULENCE TESTS.

The virulence of B C G has been tested on 88 guinea-pigs, 26 by intraperitoneal and 62 by subcutaneous inoculation, the tests covering a period of seven years. The majority of the guinea-pigs were "virulence controls," that is to say, animals which were inoculated with the strain from time to time to prove its non-virulence.

Intraperitoneal inoculations.—The doses of B C G ranged from 1·0 to 200·0 mg. Of the 26 guinea-pigs inoculated intraperitoneally two, the dose in each instance being 10·0 mg., died acutely in seven and nine days respectively, and showed at autopsy in each instance thickening and retraction of the omentum (which was composed of translucent grey tissue containing purulent foci), thickening and contraction of the mesentery, milky opacity of the parietal peritoneum, an enlarged soft red spleen, yellow necrotic foci in small number in the substance of the liver (both organs showing grey tuberculous foci on the surfaces), and necrosis of the sternal glands;

both liver and iron were given. This observation, while perhaps adding to the complexities attending the investigation of anæmic cases, is of importance at a time when much light is being thrown upon the various maladies associated with nutrition.

THE CAUSATION OF PITYRIASIS ROSEA.

THE chief importance of pityriasis rosea, which is nearly always a mild and non-disabling eruption, lies in its differentiation from secondary syphilis, with which it is still occasionally confused. The careful experimental work of Dr. M. Sydney Thomson and Dr. J. N. Cumings[1] nevertheless deserves more than a casual reference. Of 18 cases studied since December, 1930, the famous "herald patch" was absent in only three, and only six of them showed any constitutional disturbance, manifest by a temperature up to 100° F. One patient complained of sore-throat, five showed faucial congestion, and three had glandular enlargement confined to the neck in two. Pruritus is by no means a constant feature, and only five made any complaint of it. The youngest patient was a girl aged 21 months, the oldest a woman of 77. Tuberculosis has been claimed as a possible cause by Le Damany, but his evidence is slight, and the Mantoux test in Thomson and Cumings's series was decidedly against such a hypothesis. No one believes that syphilis is a cause, and no investigator has yet demonstrated a fungus which satisfies the usual requirements of staining and culture. According to Benedek, of Leipzig, who has been working on the occurrence and pathogenicity of the *Schizosaccharomyces hominis*, and who took the trouble to present his view and his specimens before the Association of British Dermatologists at Bristol last year, pityriasis versicolor follows supersensitisation of the skin with this organism. But his assumptions have not been confirmed by other workers, and in a series of 24 experiments according to his technique Thomson and Cumings record negative results. Blood counts appear to have revealed "a definite tendency to leucopenia with relative lymphocytosis." This appearance is accentuated in the comparative tables of counts in this disease and 20 consecutive cases of other skin diseases. The type of blood picture resembles that met with in vaccinia, alone among the acute specific fevers, and "may therefore have some significance," they think, in the ætiology. Tests along the lines devised by Dick for scarlet fever—the material being obtained from the scales of a herald patch and added to 10 c.cm. normal saline—gave a positive reaction in 11 out of 13 healthy persons who had never had the disease, in four out of five cases of other skin disease, and only in one case definitely out of ten just recovering from the typical eruption. These results seem to indicate that the cause of the disease is a living virus; yet attempts to inoculate the disease into other subjects all failed. (Wile succeeded four times after many attempts.) After some discussion based on their results Thomson and Cumings come to the conclusion that these point to a virus as the cause of the disease, and agree with Lassar's original hypothesis that it is probably conveyed by the vest or underclothing in immediate contact with the skin. All the suspected garments were of wool or silk and wool, except in one case where the herald patch appeared on the side of the neck soon after wearing a new fur. Two new points which emerge from the investigation will both require confirmation before they can be accepted by the dermatological world. They are the more or less constant leucopenia, with relative lymphocytosis, in convalescent cases, and the similar frequency of negative reactions to intradermal injections of saline extracts of pityriasis rosea scales in patients recently recovering from the eruption.

FUEL AND SMOKE.

ON Monday afternoon Sir Hugo Hirst, President of the Institute of Fuel, handed the Melchett medal for 1931 to Prof. W. A. Bone, of the department of chemical technology of the Imperial College of Science, for the most outstanding work in connexion with fuel. The first award of the medal was made last year to Dr. K. Rummel of Dusseldorf. Prof. Bone has given his life to the study of economy in the consumption of fuel and in the lecture which he delivered after receiving the medal he noted as one of the triumphs of mechanical science that iron could now be produced in a blast furnace at about one fifth the cost in fuel of a century ago. What this economy means to the composition of the air we breathe may be realised by considering that each of us consumes, as he put it, about 500 pounds per annum of iron and steel. The direct fuel saving on the whole world's present output of iron cannot be less than 100 million tons of coke per annum. Yet there is still in all conscience enough solid matter suspended in the air. The Seventeenth Report on Atmospheric Pollution[1] puts it at 550 tons per square mile deposited or brought down by rain each year at one point in Lancashire, and an average of 200–300 for the whole country. The report offers little hope of further improvement in London for many years to come. Indeed, there has lately been a threefold increase in sulphur deposited in such widely separated parts as Ravenscourt Park and Finsbury Circus, and sufficient smoke is still emitted in London during two or three hours of a winter's morning to produce the blackest fog of which we have any experience. Were the emission reduced by one-third we are promised nothing more than delay in the formation of the same fog. Charing Cross is held to be one of the smokiest spots in London and we may take a wry satisfaction in the assurance that the smoke haz in London is far worse than in many industrial centres. The atmosphere at Coventry is singled out as unusuall pure for a city of its size. The fog blanket moreover is not borne entirely by those who make it. Th polluted atmosphere of a town two miles in diamete is clearly to be discerned at a distance of five or si miles down wind; that of one of our monster industri areas of 24 miles in diameter would be perceptib at a distance of 60 to 70 miles, say from London Eastbourne. But in spite of all this the law relati to smoke abatement is pretty much a dead lett in many areas. There is only one district which h a statutory regional authority, and the proposal to set up a joint board in South-East Lancashire has been postponed owing to present financial difficulties. The National Smoke Abatement Society sees our best hope in the formation of advisory committees in areas where no action has at present been taken. Smoke knows no boundaries, the recent report remarks, and the efforts of one authority may be largely nullified by the inaction of adjoining authorities.

DR. William Rees Thomas has been appointed a senior commissioner of the Board of Control.

[1] Department of Scientific and Industrial Research. Report on Observations for the Year ended March 31st, 1931. H.M. Stationery Office. 5s. 6d.

SORPTION OF B C G FROM THE ALIMENTARY TRACT OF THE GUINEA-PIG.

Twenty-six guinea-pigs were fed with B C G by ette, the doses varying from 30 to 200 mg. urteen of the guinea-pigs were young, weighing m 70 to 110 g.; the remainder ranged in weight m 140 to 700 g. The guinea-pigs were killed er intervals varying from 5 to 84 days, and cultures re sown with emulsions of glands from the neck and e mesentery, and in some instances with spleen lp also.

Sixteen of the guinea-pigs were fed once with C G, the doses ranging from 45 to 150 mg., and ere killed 5 to 84 days later. In 11 of these experi-ents—duration, 5, 7, 8, 8, 14, 15, 28, 28, 31, 56, and 4 days—all the tubes sown remained sterile. In e five remaining experiments, lasting 19, 30, 44, 56, d 84 days respectively, the submental (one case) r the mesenteric glands (four cases) yielded cultures f B C G. In two of the guinea-pigs (19 and 84 ays) the bacilli were numerous in the glands; in he remaining three the number of living organisms resent in the glands was very small; for example, n one of the guinea-pigs (44 days) the whole of the nesenteric glands was used and produced only seven olonies.

Nine guinea-pigs were fed twice or three times with B C G on consecutive days, the total B C G given varying from 30 to 105 mg., and were killed 5 to 31 days after the first dose. Cultures from seven guinea-pigs, many of them young, killed 5 to 11 days after the first dose remained sterile. From two guinea-pigs B C G was recovered in culture; in one instance (six days) only one colony was obtained, while in the other (31 days) 32 colonies were obtained from the submental, and 40 from the mesenteric glands.

The remaining guinea-pig was fed five times during a period of 32 days and was killed 49 days after the first, and 17 days after the last dose. Colonies in moderate number were obtained from the submental glands and none from the mesenteric glands and spleen. In the four instances where spleen was used cultures were negative.

Acid-fast bacilli were very numerous in smear preparations of the fæces passed by guinea-pigs during the first two days following administration of B C G. They were not found on the fourth day in three guinea-pigs but were still present on the sixth, eighth, and eleventh days respectively in three further guinea-pigs.

These observations showed that B C G was abundantly present in the fæces of guinea-pigs during the first two or three days after oral administration, and in one instance was not completely eliminated from the intestinal canal on the eleventh day. Yet very few bacilli appear to have passed through the alimentary mucous membrane as is indicated by the failure in 17 out of 26 cases to cultivate the organism from the glands of the alimentary tract.

Many of the negative results were obtained with guinea-pigs which, though not new-born, were very young, seven weighing 70 to 80 g. (five negative) and eight weighing from 105 to 180 g. (seven negative). These results therefore do not support Calmette in his opinion that the alimentary mucous membrane of young animals has, in general, a greater penetrability for bacteria than that of older animals.

Since my experiments were completed Wethmar and Brunzema [5] (1931) have reported that in their feeding experiments on guinea-pigs with B C G only a very small proportion of the ingested bacilli succeeded in passing from the alimentary canal to the neighbouring glands, and that in this respect there was no difference between new-born and older guinea-pigs.

Experiments on Rabbits.

Inoculation experiments.—Inoculated subcutaneously in a dose of 50·0 mg. B C G gives rise in the rabbit to a local abscess only; the adjoining glands and the internal organs remain free from lesions. The bacilli do not long survive in the local lesion or in the adjacent (scapular) glands to which they are carried by the lymph, as the following cultural experiments show. A rabbit died 37 days after subcutaneous inoculation of 50·0 mg. of B C G and cultures were obtained from the local lesion and scapular glands. A second rabbit was killed 61 days after inoculation; pus from the local lesion sown on several tubes yielded only one colony, while the scapular glands yielded none. A third rabbit was killed 111 days after inoculation; cultures from the scapular gland remained sterile.

After intravenous inoculation B C G sometimes produces very severe effects which may result in death. Twenty-four rabbits were inoculated intravenously with the culture, the doses ranging from 0·25 mg. to 50·0 mg., and of these 12 died in from 7 to 19 days of consolidation of the lungs. In the more acute cases—death within eight days—the lungs were almost completely consolidated and uniformly grey or reddish grey, the condition resembling that which follows intravenous inoculation of dead tubercle bacilli. In rabbits which died in from 12 to 19 days after inoculation the consolidated lung was beset with yellow necrotic foci and there were definite miliary tubercles, many with opaque centres. Other morbid appearances in acutely infected rabbits were enlargement and congestion of the tracheal glands and enlarged soft red spleen; grey follicular tubercles were seen occasionally in the liver. Tubercle bacilli were not numerous in smear preparations from the lung, except after very large doses, and were usually scanty in the other organs. Of the 12 acutely affected rabbits six were young, weighing from 250 to 700 g., and the doses of B C G ranged from 0·25 to 5·0 mg.; six weighed from 1350 to 2070 g. and the doses ranged from 10 to 50 mg.

Ten rabbits were killed 150 to 920 days after inoculation; they were in good health and had gained greatly in weight. Four of these rabbits were from one litter a month old, and each weighed about 200 g. They received doses of from 0·25 to 1·0 mg. and were ill for some weeks. Two were killed 150 days after inoculation and showed no sign of disease. The other two were killed after 920 days; one was normal except for two calcareous foci of doubtful origin in the mesenteric glands; the other showed in the lungs evidence of previous severe inflammation in the form of ramifying superficial fibrous thickenings on the surface and thickening of the interstitial fibrous tissue. Three other rabbits from this litter, inoculated with 0·25, 0·75, and 1·0 mg. B C G respectively at the same time as these four, died within three weeks of pneumonia and miliary tuberculosis of the lungs.

Two adult rabbits received 2·0 and 1·0 mg. of B C G and were killed 590 days later; there was no sign of tuberculosis in either of these rabbits. In the remaining four rabbits, killed 159 to 215 days after inoculation, scattered minute grey tubercles, some opaque and containing acid-fast bacilli, were found in the lungs.

These experiments have shown that the intravenous in one guinea-pig the pleural cavities were filled with fluid and the lungs were collapsed.

The death of these guinea-pigs was due, I think, to the irritant and toxic action of the bacilli which, as shown by cultivation experiments, were disseminated over the body.

One guinea-pig died in ten days as a result of intestinal obstruction from peritoneal adhesions; a sternal gland was slightly caseous; otherwise there were no macroscopic lesions. Another guinea-pig died in 176 days of ascites due apparently to extensive adhesions of stomach and intestines to each other and the parietal wall; there were no tuberculous lesions in the organs or glands. No other guinea-pig inoculated intraperitoneally with B C G died as a result of the injection, the duration of the experiments ranging up to 421 days.

Autopsies on guinea-pigs which had lived some time after intraperitoneal injection of massive doses of B C G showed the omentum converted into a band of fibrous tissue adherent to the stomach, and sometimes to the intestines, and containing one or two collections of creamy pus in which acid-fast bacilli were abundant. There were often small abscesses in other parts of the abdomen—in the splenic omentum, between the coils of the intestines and on the liver or parietal peritoneum—and fibrous adhesions between the viscera and the parietes. In male guinea-pigs the scrotal sacs always contained creamy pus which was locked in by peritoneal adhesions, and in some instances was the cause of atrophy of the testes and epididymes.

Tuberculous lesions have never been seen in the abdominal and thoracic organs and glands of guinea-pigs which have survived an intraperitoneal inoculation of B C G.

Subcutaneous inoculation.—A massive dose—10 to 400 mg.—of B C G in the subcutaneous tissues of the abdominal wall gives rise to a swelling of varying size. At first firm, the swelling soon begins to soften and becomes an abscess. This ulcerates the skin, usually about the tenth day, and discharges its caseopurulent contents. The ulcer rapidly heals and cicatrises, and no trace is visible two to three months later, except perhaps a white scar. The adjacent inguinal glands undergo enlargement which in most instances is slight and transient, generally subsiding completely within four to six weeks; sometimes the enlargement is more definite and persistent, but eventually it always subsides. The glands never become adherent to or ulcerate the skin.

None of the 62 guinea-pigs inoculated subcutaneously died as a result of the injection or showed visceral lesions, although many received the relatively enormous doses of from 50 to 400 mg. Five died after parturition or from intracurrent affections. The remainder having gained in weight were killed in from 14 to 617 days.

Autopsies on guinea-pigs killed within about five weeks of subcutaneous inoculation generally showed at the seat of inoculation a small healing ulcer, or occasionally a subcutaneous collection of caseopus. The inguinal and sometimes the sternal glands were slightly enlarged and perhaps congested and showed possibly one or two foci or areas of necrosis. After six weeks the adjacent glands were normal in size and generally in appearance, but in five out of 51 guinea-pigs they showed a focus or two of pus.

SURVIVAL OF B C G IN THE BODY OF THE GUINEA-PIG.

The viability of B C G after injection into the guinea-pig has been tested by sowing egg and glycerin egg tubes with emulsions of different tissues, or with p from inoculation and glandular abscesses.

The organism has been recovered in culture from the pus of abdominal and scrotal abscesses of the guinea-pigs inoculated intraperitoneally. The duration of life of these animals ranged from 32 to [illegible] days. In two instances—the experiments having lasted 79 and 82 days—the abdominal pus, though containing numerous well-formed bacilli, yielded only one and two colonies of B C G respectively, several tubes having been sown, while in four instances—the duration of the experiments ranging from 70 to 79 days—numerous colonies of B C G were obtained from scrotal pus. No colonies of B C G were obtained from the abdominal or scrotal pus of five guinea-pigs killed 108, 127, 290, 319, and 421 days after inoculation.

After subcutaneous inoculation of cultures most of the bacilli remain at the seat of inoculation where they produce an abscess, but some are carried in the lymph stream to the adjacent glands or are disseminated over the body by the blood. Three to four-weeks after inoculation living B C G in moderate numbers may be demonstrated by culture in the inguinal glands of the guinea-pig, and may also be found, though in much smaller number, in the liver and the spleen. Thereafter there is a rapid fall in the number of viable organisms. The bacillus has been recovered in culture from the spleen of a guinea-pig five weeks after inoculation, but not after longer periods—namely, 6, 8, and 10 weeks.

Cultures of B C G have been obtained from t macroscopically unchanged inguinal glands of sev guinea-pigs which had been inoculated subcutaneou *40, 46, 49, 81, 86, 101, and 103 days* previou In each instance the total number of colonies obtai on the several tubes sown was very small, rang *from two to six.* No colonies of B C G were obtai from the inguinal glands of 24 guinea-pigs killed in from *59 to 92 days* (seven instances) and *111 to 558 days* (17 instances). None of these 31 guinea-pigs showed lesions in the glands or in the organs.

The autopsies on five guinea-pigs inoculated subcutaneously, as previously mentioned, revealed purulent lesions in the inguinal glands. In one of these guinea-pigs, killed 81 days after inoculation, *one purulent focus* was found in an inguinal gland; the whole of the pus was used for cultures and yielded *one colony of B C G only.* In two guinea-pigs, killed 204 and 388 days after inoculation, the pus was sterile. *One guinea-pig,* which was injected in the *deep tissues of the groin* with B C G together with dead human tubercle bacilli and killed 103 days later, showed a small local abscess and no disease elsewhere; the pus yielded half a dozen B C G colonies, *but* emulsions of the inguinal and iliac glands proved sterile.

These cultivation experiments show that the life of B C G in the body of the guinea-pig is comparatively brief. There is possibly some multiplication of bacilli for a period after inoculation, but this evidently soon ceases and the bacilli gradually die. In a few instances numerous colonies were obtained *from* abdominal pus 10 to 11 weeks after *inoculation,* but generally the number of colonies yielded by pus or tissues was small. The longest period elapsing between the inoculation of the guinea-pig and the recovery of the bacillus in culture was *103 days.* Br. Lange [4] was unable to recover the organism in culture from an animal of any species six weeks after inoculation.

astinal gland was a little enlarged. Nothing abnormal here. Moderately numerous B C G colonies from the astinal glands.

oat 122, a nanny, was inoculated intravenously 100·0 mg. B C G and died 63 days later.

ropsy.—The lungs were congested and slightly œdema- ; minute grey tubercles, some with calcareous centres. sparsely distributed throughout the parenchyma. e were *no lesions elsewhere.* A moderate number of G colonies were obtained from lung tubercles and a from a mediastinal gland.

oat 120, a nanny, was inoculated intravenously h 10·0 mg. of B C G. The goat yielded about int of milk daily during the first three weeks after ich the yield rapidly diminished and her health l appetite became poor. She died 82 days after culation.

utopsy.—Lungs patchily hepatised showed grey areas of minous pneumonia and a few grey points but no definite ercles. The mamma contained small quantities of milk, k on left side, normal on right. No T.B. were found in ear preparations and cultures from the milk and various ans and glands did not yield B C G colonies. A guinea- inoculated with milk remained healthy and cultures m its inguinal glands were negative.

SUMMARY:

Eleven goats were inoculated intravenously with C G, the doses ranging from 5 to 100 mg. Nine the goats died—two in 7 and 15 days and seven in om 27 to 101 days—and two were killed 127 and 24 days after inoculation. The two latter and six f the nine fatal cases showed no macroscopic uberculous lesions, and B C G was not recovered om the tissues.

In the remaining three goats there were definite uberculous lesions. In one goat, an adult, the esions (pulmonary) were minute and retrogressive. n the other two, both young animals, the B C G organisms had established themselves and multiplied abundantly—in the intercostal lymphatics of Goat 115, producing small tubercles with necrotic centres, and n the portal gland of Goat 116, causing necrosis without formation of giant cells. The organisms were still, apparently, actively multiplying at the moment of the death of the goats, and one cannot say what would have been the fate of the bacilli if the animals had lived. Presumably, since animals (goats and guinea-pigs) inoculated with the B C G cultures recovered from these goats showed no lesions at all when killed, the organisms would have remained localised and eventually have died out.

It is interesting that 9 out of 11 goats died after inoculation and on necropsy, except in the two adult cases, showed no apparent cause of death. This may, therefore, have been toxæmia from the liberated endotoxins of disintegrated B C G.

Experiments on Fowls.

Seven fowls were inoculated with B C G, three intravenously (doses 10, 50, and 50 mg.), and three intramuscularly (doses 40, 100, and 100 mg.).

The intravenously inoculated fowls were killed 113, 134, and 135 days later respectively, and were found to be free from tuberculous lesions. The intramuscularly inoculated fowls were killed after 112, 162, and 603 days. They showed in the pectoral muscles yellow necrotic substance surrounded by fibrous tissue and containing masses of acid-fast bacilli. In one of the fowls (603 days) the capsule of the liver showed some half-dozen greyish-white flattened tubercles, and a narrow band of fibro-caseous substance around the thin margin, evidently due to bacilli which had leaked from the pectoral muscles into the abdominal cavity; acid-fast bacilli were present but were not numerous.

Cultures from the local lesions and organs of the intramuscularly inoculated, and the organs of the intravenously inoculated fowls remained sterile.

These experiments show that B C G is not virulent for the fowl and soon dies out locally and in the organs.

Experiments on Calves and Monkeys.

The results of inoculation, feeding, and immunity experiments on calves and monkeys have already been published.[6] [7]

The Virulence of B C G after Residence in the Animal Body.

The use of a living attenuated strain of tubercle bacilli as an immunising agent against tuberculosis in man and the bovine animal has been deprecated on the ground that the bacilli might regain their original virulence during residence in the tissues of the new host.

Attenuated bovine viruses may, as I have shown [8] [9] be restored to full virulence by passing the bacilli through the bodies of calves, goats, or rabbits, and the question naturally arose whether B C G, believed to have been originally a virulent bovine strain, might not similarly become enhanced in virulence after a long period of residence and latency in the animal body.

Passage experiments with B C G are peculiarly difficult to perform because the bacilli gradually die out in the animal body and cannot with certainty be recovered in culture if the passage animal is allowed to live longer than three or four months.

As previously stated, B C G has been recovered in culture from a large number of animals of the various species inoculated with it—namely, the calf, rabbit, goat, guinea-pig and monkey. Of the total number of these strains 17 were tested as to their virulence for the guinea-pig, but none produced more than the slight local effects which have followed the injection of the original culture. Single residences, therefore, in the calf (27, 47, and 72 days), rabbit (37 and 61 days), guinea-pig (up to 103 days), goat (48 and 189 days), and monkey (180, 190, and 206 days) caused no increase in the virulence of B C G.

The majority of the guinea-pigs used to test the virulence of B C G recovered from the animals mentioned were allowed to live many months, and for this reason cultures from their tissues were negative. From six guinea-pigs, however, which were killed within 12 weeks B C G was again recovered in culture, and each of these strains was tested on the guinea-pig. Four of the six guinea-pigs, when killed, showed no lesions and did not yield cultures. From the remaining two, cultures were obtained which were passed through other guinea-pigs in series. In one of these experiments after five passages (285 days) the bacilli died out. The other is still in progress. In a few instances B C G was inoculated into a guinea-pig or a rabbit along with killed bovine, human or avian tubercle bacilli. These experiments are not completed, but have not so far produced any increase in the virulence of the organism.

The results of the passage experiments are in agreement with those of Calmette,[10] Kraus,[11] [12] Gerlach,[13] Br. Lange [14] and others, and show that B C G has a high degree of stability in the animal body. While the experiments have not been of sufficiently long duration for one to conclude that the characters of B C G are absolutely fixed, they nevertheless show conclusively that the strain used by me does not contain a virulent element, and is therefore different from those employed by Petroff and Watson.

inoculation of B C G produces in the rabbit a definite tuberculosis. The lesions, however, although more distinct and lasting than in the guinea-pig have, like those in the latter species, no progressive tendency. There is a critical period in the life of a rabbit inoculated intravenously with B C G in which the animal may die; this in my series has varied from 7 to 19 days. Autopsies in these cases have shown that the cause of death is pneumonia, due, I think, to the irritant and toxic action of the bacilli. If the pneumonia is not so extensive as to cause death mechanically the animal recovers; the cellular exudate in the pulmonary alveoli is rapidly absorbed and after five or six months no trace of the infection is left or only slight traces in the form of isolated miliary, encapsuled or calcified tubercles or, as in one rabbit, scar tissue. Whether a rabbit dies or recovers from an intravenous inoculation of B C G appears to depend more upon the susceptibility of the rabbit than on the dose. Rapidly fatal tuberculous pneumonia has been produced in young rabbits by such small doses as 0·25 and 1·0 mg. and in older animals by doses of 4, 10, 20, and 50 mg. while other animals of equal age inoculated at the same time with these doses have survived.

Joint lesions, which occur so frequently in rabbits chronically infected with bovine, human or avian tubercle bacilli, have not been found in any of the rabbits inoculated with B C G.

Feeding experiments.—Seven young rabbits were fed with B C G. One rabbit, 17 days old, received by pipette 100 mg. of B C G as a single dose and was killed 14 days later. The glands of the neck and mesentery were emulsified and used to sow cultures. Two colonies of B C G were obtained from the submental glands; none from the submaxillary and mesenteric glands. (At the same time a member of the same litter was fed with 60·0 mg. of avian bacilli and was killed 14 days later. Cultures from its submental, submaxillary, and mesenteric glands yielded numerous colonies of avian bacilli).

Four rabbits, members of one litter, 9 days old, were fed repeatedly with B C G. One received 195 mg. in six doses during 25 days and was killed 36 days after the first dose. Cultures from the submental glands yielded six colonies of B C G, from the mesenteric none. The remaining three, which received from 225 to 245 mg. in seven doses, were killed 774, 799, and 800 days after the first dose. In one there was no sign of tuberculosis, while two showed one minute opaque focus and a few minute calcareous foci respectively in the mesenteric glands.

One rabbit, 36 days old, received 462 mg. of B C G in nine doses during 29 days and was killed 37 days after the experiment began. Twenty colonies of B C G grew on one egg tube (all others contaminated) sown with an emulsion of neck glands, and none on tubes sown with mesenteric glands.

The remaining rabbit, 15 days old, received 355 mg. in three doses at intervals of a few days and was killed 56 days after the experiment began. All the tubes sown from the glands of the neck, mesenteric glands and spleen remained sterile.

In these experiments on rabbits an extremely small proportion of the ingested B C G was absorbed from the alimentary canal. As stated above B C G was cultivated only from the submental glands of the rabbits. This circumstance is attributable to the method of feeding by pipetting the emulsion between the lips without opening the jaws, resulting in a temporary lodgment of many of the bacilli in the cheek pouches and the teeth sockets. In one rabbit bacilli were numerous in a fæcal pellet passed 48 hours after feeding. The failure to find the bacilli in the mesenteric glands indicated, therefore, that the absorption, if any, from the intestinal canal was very scanty.

The experiments of long duration show that B C G when they reach the mesenteric glands of rabbits may produce trivial local lesions which, however, have no progressive tendency and eventually heal.

Experiments on Goats.

On July 27th, 1926, a kid was inoculated intravenously with 50·0 mg. B C G. It died 15 days later of intestinal coccidiosis. The lungs were crepitant and perhaps a little congested, but were not otherwise abnormal; other organs (except the intestines) and the lymphatic glands were normal.

On Dec. 21st, 1926, four young goats, about 6 months old, were inoculated intravenously each with 50·0 mg. B C G.

Goat 113 died seven days after inoculation of hepatisation of the lungs.

Goat 114 was killed 127 days after inoculation. The autopsy showed no sign of tuberculosis. No T.B. were found in smear preparations.

Goat 115 was killed moribund 143 days after inoculation.

Autopsy.—The lungs showed scattered yellow gritty tubercles, 0·5 mm. in diameter and some minute grey points. Two thoracic glands each contained a minute yellow focus (T.B.). The portal glands showed two gritty foci. Kidneys, a few doubtful grey points. The intercostal lymphatic vessels along the posterior margins of some of the rib showed greyish-yellow tubercles 0·5 to 1·0 mm. in diameter in places they formed chaplets about 2 cm. in length; i other places they were sparsely distributed, some lymphatic showing only one or two. Microscopically these tubercl showed a thick fibrous wall and a necrotic central part i which tubercle bacilli were extremely numerous, occurri chiefly in dense masses. Cultures from these tubercl yielded abundant colonies of B C G; a few colonies B C G were obtained from the mediastinal and mesente glands. A guinea-pig inoculated subcutaneously with 50 m of the intercostal strain died in 48 days, but showed no si of tuberculosis.

Goat 116 died 76 days after inoculation.

Autopsy.—Lungs showed about a third of each cau lobe red and hepatised and elsewhere isolated red and airl lobules; the parenchyma seemed firm and the interlob septa were distinct. The thoracic glands were not obvio enlarged but they were firmer than normal; there were tubercles. Spleen and liver normal. Portal glands seen slightly enlarged and firmer than normal and showed un the capsule a mosaic of greyish-yellow foci or follicles ab 1 mm. in diameter. Kidneys showed a few grey foci doubtful nature. No T.B. were found in lung mediastinal gland; they were numerous in portal gland.

Cultures: A few colonies were obtained from the l and bronchial gland and moderately numerous colonies f the spleen and portal glands. Two guinea-pigs inocul subcutaneously with emulsion of portal glands were fo to be perfectly healthy when killed 218 days later, cultures from the inguinal glands of one remained steril

A guinea-pig inoculated subcutaneously with 25·0 m culture of the portal gland strain was killed 189 days and found to be free from disease; cultures from the ingu glands remained sterile. The culture from the portal g was also tested on two goats by intravenous inoculatio 10·0 mg. The goats died 96 and 101 days later but nothi a tuberculous nature was found in either and microsco examinations and cultures from various organs and gl were negative.

Goat 119, a kid 2½ months old, received 5·0 B C G intravenously.

The animal was killed 324 days later and showe signs of tuberculosis; cultures from an interbronchial g remained sterile.

Goat 121, a nanny, was inoculated intraveno with 100·0 mg. B C G and died 27 days later.

Autopsy showed the lungs expanded and a little cong and œdematous; there were no tubercles. The will be recalled that the Coroners (Amendment))f 1926 abolished franchise coronerships from the of the next vacancy and made fresh provision the rearrangement of districts. Two county ners in London happened to hold franchise ·icts—namely, the districts of the Duchy of caster (Clapham and the Savoy) and Westminster. y resigned their franchise coronerships in order ·eate a vacancy, and the retirements of Mr. Oswald Sir Walter Schröder were made the occasion of a eral review of coroners' districts by the London nty Council. Following the procedure prescribed Section 12 of the 1926 Act, the London County ncil submitted a draft order for a redistribution the coroners' districts of the county. Their eme, which was confirmed in November, 1930, hout substantial variation, reduced the number listricts from seven to six and promised an economy ibout £200 a year. The district which disappeared s the north-eastern division. Where formerly ere were separate eastern, north-eastern, and south-stern districts, there are now an eastern and a ith-eastern district; the latter includes the tropolitan boroughs of Bermondsey, Deptford, eenwich, Lewisham, and Woolwich. The scheme t outstanding, pending the occurrence of vacancies, e franchise coronerships of the Liberty of the wer (part of Stepney in the eastern district) and Southwark (partly within the metropolitan boroughs Lambeth and of Southwark in the southern district d partly in Bermondsey in the south-eastern strict). The intention was that these excluded land areas should be merged in their surroundings ·hen the next vacancy brought the franchise to an nd.

THE SPAHLINGER METHOD FOR THE PREPARATION OF SPECIFIC ANTIGENS.

THE following statement has been supplied by Mr. Henry Spahlinger in order that the method described may be explored in other fields of research.

Principles on which the Method is Based.

The object is to prepare in vitro antigens identical to those generated by a given pathogenic micro-organism in the living body of human beings or of a given animal species in which this micro-organism gives rise to disease. These specific antigens will stimulate the production of antibodies and anti-micro-organism defences identical with those which are elaborated in the living body when it is successfully overcoming disease.

In order to prepare such antigens, the appropriate pathogenic micro-organisms are isolated from an infected subject, without being passed through another animal species, because this might alter their specificity by adaptation to a different zoological species. These micro-organisms are thereafter cultivated under conditions as similar as possible to those present in vivo. This is done on *specific* culture media, which will supply *specific* biochemical material, identical with that provided in vivo, thus enabling these micro-organisms to retain and reproduce in vitro specific protoplasm, metabolism, secretions, aggressive and defensive means, and a specific progeny.

The standard of specificity is set up by the antigenic structure elaborated by a given micro-organism when developing under normal spontaneous conditions in a human or animal body wherein this micro-organism causes the disease which the antigen is directly (active immunity) or indirectly (passive immunity) intended to prevent or cure.

In addition, no chemical or physical reaction or manipulation may be employed, either during or after the preparation of the antigens, which might alter or denature, even to a slight extent, the antigenic specificity.

Method of Preparation of Antigens for the Preventive Immunisation of Cattle against Tuberculosis.

A piece of tuberculous material is excised in a sterile manner from a lesion of one of the dead bovine cattle at a slaughter-house. Tuberculous micro-organisms taken from this material are then inoculated, under sterile conditions, on *specific* media which will supply the micro-organisms with specific *bovine* biochemical material.

The specific culture medium is prepared as follows:

A bovine body fluid (defibrinated blood, serum, organ or tissue extract, &c.) is distributed in test-tubes, made of Jena glass. These test-tubes are thereafter placed, in a sloping position, in an incubator, and the liquid is coagulated at about 65° C. When the tubes and their contents have become cold, there is spread on the coagulated surface of this solid medium a small quantity of normal (non-heated) bovine body fluid (defibrinated blood, serum, organ or tissue extract, &c.); the tubes are then placed in the same inclined position as they were in the incubator, so that the normal bovine fluid well covers the whole surface of the coagulated medium. The tubes are left 18 hours in this position, so that the normal bovine fluid can well impregnate the superficial layers of the coagulated medium.

These specific media, inoculated with native bovine tubercle micro-organisms—i.e., unaltered by passages on artificial media or by passages through an animal species zoologically heterogeneous to bovine cattle—are placed in an incubator where they are kept in the dark at a temperature of 38·5° to 39° C.

As soon as the culture has sufficiently grown, it is reinoculated on specific normal (unheated) bovine media, preferably liquid, consisting of normal defibrinated blood, serum, organ or tissue extract, &c., of bovine cattle, contained in Jena glass flasks. These cultures are then placed in a dark incubator and kept at a temperature of 38·5° to 39° C. When the cultures have sufficiently developed, the tubercle micro-organisms are collected and made into an emulsion in a sterile manner, in the absence of oxygen, with distilled water or normal saline solution.

The emulsion is thereafter distributed into ampoules, put away, and kept in a cool, completely dark place until all the tubercle micro-organisms in the emulsion have died a *natural death* by the efflux of time. According to the nature of the emulsion (its concentration, state of division of the tubercle micro-organisms, &c.), it is necessary to keep the vaccine a considerable time—a year or even longer—before it can be used. It is then a harmless—though effective—material for preventive immunisation.

The antigens thus prepared in vitro are identical with those elaborated by the tuberculous micro-organisms in vivo in diseased bovine cattle, save that the former antigens, when ready for use, will *not* be part of a *living* micro-organism.

Each batch of vaccine must be tested so as to be quite certain that the micro-organisms are indeed dead. Traces of antiseptics, formaldehyde for instance, may be added to the emulsion before sealing it in the ampoules, but every precaution must be taken to safeguard the strictest specificity of the antigenic elements. The vaccines thus prepared retain for years their specific antigenic and vaccinating properties.

It is essential that, from the moment of the isolation of the tubercle micro-organisms and during all the subsequent processes, no reaction or manipulation should take place which might alter, even in a slight degree, chemically, physically, or physiologically, the bacterial metabolism and the antigenic structure of the unmodified bovine tubercle micro-organisms.

The vaccine embodies different bovine strains of tuberculosis.

Summary.

B C G grows luxuriantly on ordinary solid media, producing dry coherent crumbly masses, difficult to emulsify. The cultures closely resemble those of the human tubercle bacillus.

The strain can produce tuberculous lesions in guinea-pigs, monkeys, rabbits and goats. These lesions, however, have not a progressive tendency and after a time they heal, or become obsolescent, the bacilli contained within them dying out.

In large doses intravenously (or intratracheally) the strain has caused in rabbits and monkeys death from tuberculous pneumonia, but this was due to the irritant action of the bacilli and was similar to that which follows the intravenous inoculation of large doses of dead bacilli.

The strain has retained its cultural characteristics and has not become increased in virulence after continuous cultivation on ordinary egg and glycerin egg media for a period of upwards of eight years, or during long residence in the body of an animal, or after passage through a series of animals.

The results of my investigations support the contention of Calmette that B C G may be used as a vaccine without risk of causing progressive lesions.

(*To be concluded.*)

MEDICINE AND THE LAW.

Unqualified Practitioners and the Title of "Doctor."

AFTER several days' trial at the Old Bailey last week, Rupert Charles Handley Ensor, 51, was found not guilty on charges which alleged that he falsely represented himself to be a duly registered medical practitioner and thereby obtained sums of money from patients. As prosecuting counsel explained, it is not an offence for an unqualified man to practise, but it is an offence for him to obtain fees from patients by making them believe that he is qualified when in fact he is not. One witness from whom it was alleged that £133 had been obtained stated that he saw Ensor standing on the steps of St. Mary's Hospital and that Ensor told him he was a surgeon on the staff. Counsel for the accused gave the following account of his history. Ensor was the son of a clergyman and was trained for the church. He graduated at Cambridge, became a clerk in Holy Orders and served as a chaplain during the war, also obtaining a commission in the Royal Air Force. Ensor, said his counsel, was not a quack but had had medical training. The accused gave details on this point in his evidence. He had passed his third examination for the M.B. degree in 1926, at Queen's University, Belfast, had experience in various hospitals, and obtained his "public vaccinator" certificate in 19[illegible]. In 1931 he took a course in surgery at St. Mary's Hospital Medical School and University College Hospital Medical School. He had been practising for three years. Almost all his patients suffered from varicose conditions of the legs and ulcers arising from those conditions. He treated about 80 patients a week with a solution which he had discovered.

There was some dispute in the case as to whether the accused *called himself "doctor"* or not. He denied the suggestion but admitted that his patients might have given him that title. The Recorder explained to the jury that the registered medical practitioners had no monopoly either of the healing art or of the title "doctor." There were doctors of science, medicine, divinity, literature, music, and other branches of learning. The true issue was whether Ensor had falsely represented himself to be a duly qualified medical man and, in calling himself "Dr. Ensor," had sailed under false colours. As already stated, the accused was acquitted of all the charges.

Overdose of Allonal.

At an inquest at Birmingham on the death of Mrs. Mary West, of Erdington, a verdict was returned of death from misadventure through an overdose of allonal self-administered. The coroner (Dr. W. H Davison) stated that a chemist had supplied th deceased in a year and thirteen days with 3716 tablet of allonal, approximately ten a day. Medical evidenc was given to the effect that the minimum fatal do would be 50 tablets and that death was caus by broncho-pneumonia supervening on narcot poisoning. The coroner observed that there w ample justification for the view that the chem should have consulted the prescribing doctor. Had done so, he would have found out that the doc named was not in fact on the Medical Register. T jury added a rider censuring the chemist a advocating the stricter regulation of the sale of injurious a drug.

Rearrangement of Coroners' Courts.

The inconvenience which the London Cou Council's rearrangement of coroners' courts in south-eastern district is likely to inflict on the med profession was referred to at this week's mee of the Council, when Mr. H. Berry drew attentio the fact that the Greenwich court, allocated for c arising in the borough of Woolwich, was five n distant from New Eltham and Abbey Wood. asked the chairman of the public control commi whether the local branch of the British Me Association and the Woolwich council had ent strong protests against the proposed arrangem and whether the matter could be further consid Mr. C. J. Allpass (chairman of the public co committee) said no direct representation had received from the medical profession, but the Wool borough council had written expressing disagree and stating that the local branch of the Br Medical Association had made a protest. It was proposed, he said, to alter the present arrangem which had been in operation for some time and w the coroner assured the council had caused no in venience. The question of inquest accommodati London, was, however, still under consideration, Mr. Berry would be afforded an opportunit attending the committee when the matter discussed.

PUBLIC HEALTH SERVICES

UAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

egistered stillbirths per 100 live births: Warwickshire 4·2, folk 4·5, East Suffolk 3·4, Breconshire 5·6, Guernsey 4·0.

Warwickshire.

Dr. A. H. Wood says the nine transferred institu-ns are of the mixed type and in no case provided th a separate hospital. Relief to the mental spital at Hatton has been afforded by the transfer 30 mild lunacy cases to Alcester institution. casion has not arisen for consultation with the luntary hospitals. Two applications for help from ral districts towards water-supply schemes and one wards sewerage have been received.

The county nursing association, employing 62 urses, covers five-sixths of the county, and the emaining large rural area on the east is looked fter by the Newnham Association with six nurses. he former body undertook 786 midwifery and 290 aternity cases, and the latter 175 and 58. These urses do not attend infectious cases, except tuber-ulosis. The practising midwives numbered 219 nd summoned medical help in one out of every three of their cases. Dr. Wood enumerates the measures taken in recent years to improve the midwifery service in the county, and deplores the fact that deaths in childbirth are much as they were twenty years ago. He has suggested to his committee paying the fees of the practitioners for antenatal examinations at a cost of about £1400 per annum and paying the fees of the midwives for acting as maternity nurses, in cases where a doctor has been engaged, at a cost of about £1500 per annum. Of the 5940 births in 1930, 3172 were attended by midwives alone and 1127 by midwives acting as maternity nurses, leaving 1311 (or 23 per cent.) who were attended by doctors either alone or with nurses unqualified in midwifery or with handywomen. Surely, says Dr. Wood, the time has come for every lying-in woman to have the advantage of a nurse skilled in midwifery.

The condition of the Tame, thanks to better sewage treatment by the towns of the Black Country, improves slowly, and the account of the Avon is more hopeful still. Six rural district councils have promised grants, amounting to £3356, for the reconditioning of 61 houses under the Housing (R.W.) Act, but only four out of 14 rural districts refer to a shortage for the agricultural population.

Of the 195 beds at the sanatorium, 61 are reserved for advanced cases. Dr. Wood thinks this is a mistake, and that eventually the public assistance institutions will be able to free the sanatorium for its proper work. The orthopædic scheme comprises 12 clinics and beds at five hospitals, but two years ago, in order to lessen expenditure, the hospital beds were limited. As a result, many cases wait months for operative treatment, although beds may be available. On Dec. 31st there was a waiting-list of 23 children at one hospital and 22 at another. There are five V.D. clinics, but they fail to reach the whole of the rural population, and many patients must still be receiving unskilled treatment.

Gloucestershire.

Dr. J. M. Martin shows that in altering the county boundaries 15 parishes (population 4918) have been transferred to Warwickshire and Worcestershire, and ten parishes (population 3859) from Wiltshire and Worcestershire have been added to Gloucester. A provisional scheme for grouping of districts for appointments of medical officers of health and for isolation hospitals has been approved. The health visitors have 193 nurse-children under supervision under the Children Act. The 14 institutions transferred, of the mixed type and built about 1810, have 2500 beds including 750 infirmary beds. Except for Thornbury, with a hospital (46 beds), built 20 years ago, the infirmary beds are not satisfactory. There are four large areas now without a hospital. Three of these might be served by extensions of existing hospitals, but the fourth in the north-east should have a new general hospital, serving all classes of the community. There are 212 practising doctors, of whom 175 treat insured patients and 75 are poor-law medical officers. Dr. Martin suggests that the funds available should be divided among the practitioners willing to do the former poor-law domiciliary work on a capitation basis. Thus the insured father and his family, if in receipt of assistance, would probably have the same doctor.

About one in 30 confinements took place in hospital. Some patients had to be moved long distances, and there is need for more maternity beds in some parts of the county. An antenatal centre was opened at Cinderford in 1929, and a second at Lydney in April, 1930. The mothers made good attendances and the midwives are enthusiastic. It is intended to open a new centre every three months. Midwives attended 56 per cent. of the total births and sent for medical help in the same proportion of their cases.

The medical services scheme continues its growth. Four additional out-stations were opened in 1930. The orthopædic scheme, formerly run from Cheltenham Hospital with one surgeon, is now based on hospitals at Cheltenham, Gloucester, and Bristol, and has the services of three orthopædic surgeons. Venereal disease can now be treated at the out-stations, after

---

(*Continued from previous page.*)

of the salary suggested by the Department of Local Government and Public Health for a medical appointment in the gift of the local authority. This is, however, what has just happened at Limerick. The Department had fixed the salary of a junior house surgeon at £120 a year in lieu of £200 a year decided on by a committee of the Limerick city board of health. The board of health denounced the proposed amount as "scandalous" in view of the cost of professional education, pointing out that tradesmen working in the same institution received wages of £4 6*s*. 8*d*. a week.

With vaccines prepared by the method described above, bovine animals have been most successfully vaccinated in an extensive series of tests. Calves immunised with the bovine vaccine were subsequently injected with large doses of living bovine tubercle bacilli, which they entirely resisted; while unvaccinated calves, used as controls, rapidly succumbed, their autopsies revealing miliary tuberculosis.

Method of Preparation of Antigens for the Preventive Vaccination of Human Beings against *Tuberculosis.*

The vaccine for human beings for antituberculous purposes comprises three different types of vaccine. (1) A *bovine* vaccine (made from *bovine* tubercle micro-organisms grown on specific *bovine* media) prepared as previously described. (2) A vaccine made from *bovine* tubercle micro-organisms grown on specific *human* media.

Bovine tubercle micro-organisms are isolated from tuberculous lesions of dead cattle and grown on a solid medium in the manner previously described. They are, thereafter, inoculated on specific human media, preferably liquid, for instance, normal (unheated) defibrinated blood, serum, ascitic or pleural fluids, &c., and grown in a dark incubator at a temperature of 37·5°. When the cultures have sufficiently grown, the tubercle micro-organisms are collected and made into an emulsion, in a sterile manner, as said above.

(3) A vaccine made from *human* tubercle micro-organisms grown on specific *human* media.

Tubercle micro-organisms of the human type are isolated directly from tuberculous lesions of human beings, inoculated on human media made with defibrinated blood, serum, ascitic or pleural fluids, &c., prepared in the same way as the specific bovine solid media previously described, and thereafter grown in a dark incubator at 37·5°. If agar is added to ascitic fluid, high temperatures must be avoided. Thereafter a normal (unheated) human body fluid is spread on the surface of the solid medium, so that it can well impregnate the superficial layers thereof.

The human tuberculous micro-organisms should be isolated from a human lesion, without animal (such as guinea-pig) passage, so as to avoid adaptation to an animal species which is "foreign" in the zoological sense to the human species, and cultivated directly on a *specific* human culture medium.

When the culture has sufficiently developed on this medium, the micro-organisms are reinoculated on normal (unheated) specific human media, preferably liquid, &c. As soon as these cultures have attained their full development, the tubercle micro-organisms are collected and emulsified, in a sterile manner, as described above. This emulsion must of course embody the different strains of the human type of tuberculosis.

Distilled water, peptone, glucose, glycerin, and other substances, which do not affect the specific properties of the tuberculous antigens, can be added in small quantities to the culture media.

The human and bovine culture media employed must originate from *tuberculous-free* bodies.

It is advisable that the human body fluids be filtered before being made up into the culture media, and the tubercle micro-organisms, grown on these media, should be washed several times in a normal saline solution before being emulsified. This is in order to remove all traces of the culture medium. In addition, formaldehyde may be added to the vaccine for human beings.

The final human vaccine is a mixture of the three types of vaccines above described. The relative proportions of these three vary according to the nature of the particular type of the tuberculous disease.

Of course, human beings cannot be used as controls, or subjected to deliberate massive experimental infection (such as can be applied to cattle) to demonstrate the value of the human vaccine. Therefore conclusive evidence of the degree and duration of the human immunity can only be based on statistics covering a very large number of cases and collected over a period of years during which those vaccinated have been subjected to careful observation.

Potentialities of the Method.

According to the type of immunisation and the species of micro-organisms from which the antigens are derived, the material used should be:

(*a*) The bacterial bodies (whole endotoxins).

(*b*) An extract of the bacterial bodies (partial endotoxins).

(*c*) The specific liquid on or in which the micro-organisms have grown; this liquid containing the soluble antigenic substances (exotoxins)—products of the bacterial metabolism and of the aggressive and defensive means elaborated by the pathogenic micro-organisms.

(*d*) A mixture of (*a*) and (*c*), or (*b*) and (*c*).

There is experimental evidence indicating that this method can be successfully used against various diseases, in human beings and animals, not only for preventive and therapeutic vaccination, but also for the preparation of antitoxic and antibacterial sera, for test purposes, antigen-antibody reactions, &c.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

THE REPORT OF THE REGISTRAR-GENERAL OF THE IRISH FREE STATE.

THE report for 1930 of the Registrar-General of the Irish Free State has recently been issued. The estimated population was almost identical with that in the previous year, but less by 26,000 than in 1926, when the last census was taken. The emigration was less by 5238 than in 1929, a decrease probably due rather to diminished prospect of employment in America than to increased opportunities at home. The marriage-rate for the yea was 4·63 per 1000, as compared with 4·61 in 192 and 4·86 in the decade 1920–29. In Northern Irelan the rate was 6·07, in England and Wales 7·9, and i Scotland 6·80. The birth-rate in 1930 was 19·8 per 1000, in 1929 it was 19·78, and in the decad 1920–29 it was 20·39. The slight increase in t birth-rate in 1930 makes very little impression in t general trend of decline shown in recent years. Fro 1911–15 to 1925–29 there has been a fall of 9·7 p cent. The percentage of illegitimate births to to births was 3·19 in 1930, 2·80 in 1925–27, and 2 in 1910–12. The percentage in Northern Irela in 1930 was 5·1, in England and Wales 4·6, and Scotland 7·4. The death-rate in 1930 was 14 per 1000 of the population, a rate than which o two years show a lower record—namely, 14·01 1923 and 14·06 in 1926. The rate for tubercul continues to decline, although it is still high compared with other countries. It was 1·30 1000 in 1930, as compared with 1·32 in 1929, and average of 1·49 in the years 1920–29. The dea from cancer continued to increase, the number 1930 being 3329, an increase of 213 over the previ year. On the other hand, the deaths from dise and accidents of childbirth show a slight diminutio 4·77 per 1000 births as compared with 4·82 in previous decade. The infant mortality was per 1000 births, which was two below the rate 1929, and three below that for the decade 1920– The infant mortality among illegitimate chil is, however, appallingly high—251 per 1000, n than four times that among legitimate.

A "SCANDALOUS" SALARY.

It is unusual to find a local health autho criticising, on the grounds of its iniquity, the am

(*Continued at foot of opposite page.*)

ong infectious diseases the event of the year water-borne epidemic of enteric fever at echam. The cases of enteric in the county the last four years numbered 2, 3. 3, and 5. 30 they rose in number to 70. In the early of the year there were three cases. and in the hree weeks of September. 23. 31, and 6 cases removed to hospital. Investigation showed water was the only common factor. and later he pipes leading from the springs to one of the had faulty joints close to a land drain. One of ur farm servants was found to be a carrier. The r has worked in this area for more than three , but the chain of circumstances favourable to a -borne epidemic had evidently not occurred e, and on this occasion the water was probably infective for a few days between August 10th 14th. There were few secondary cases, which is reat contrast with the year 1895. when the ication reached a similar figure at a period when oid was endemic.

ro poor-houses, with 27 beds for the sick. transferred to the council under the Local ernment Act. Dr. Ritchie puts forward an active scheme for improving the hospital service he county. There are at present four small tion hospitals. He suggests that of these, maben should be slightly enlarged and carry all the isolation work. There would then be lable 74 beds in three modern well-constructed dings, which could be easily converted into cottage pitals and used as annexes of the four voluntary ral hospitals. thus providing for convalescence abolishing waiting-lists.

Guernsey.

Dr. H. D. Bishop says that the births during the t thirty years of the century numbered 26.919. l the maternal deaths in childbirth 55, giving a e of 2·04 per 1000 births. The deaths from erculosis in 1930 were 36, of which 35 were due to hisis and one to tuberculous meningitis. The gle death from non-pulmonary tuberculosis is eresting on account of the claimed absence of the vine bacillus. Dr. Bishop complains that lmonary tuberculosis is only sent to the sanatorium an advanced stage; he would like the other spitals in the Islands to make greater provision the isolation of advanced cases. His suggestion at the poor-law board should be renamed the mmittee for public assistance, and cease to restrict s hospital provision to paupers, may be helpful. he "homes for workers" committee has completed s housing scheme, and now lends money at a low te of interest to persons who wish to build small ouses for themselves. The chief housing need now, ys Dr. Bishop. is for cheap flats for the small umber of families who are really undesirable tenants. sum of money is voted every year for the treatment of mental defectives. and occasionally cases fter a very long delay are sent to English institutions. Dr. Bishop recommends that the Channel Islands hould establish a joint institution, with facilities or grading and education. He also advocates the ormation of a cancer care committee to undertake publicity work and render assistance to sufferers.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JAN. 23RD, 1932.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox. 55 (last week 68); scarlet fever. 1502; diphtheria. 946; enteric fever, 22; pneumonia, 1786; puerperal fever, 46; puerperal pyrexia. 108; cerebro-spinal fever. 57; acute poliomyelitis, 4; acute polio-encephalitis, 1; encephalitis lethargica. 16; continued fever, 1; dysentery. 17; ophthalmia neonatorum. 103. No case of cholera. plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Jan. 26th–27th was as follows: Small-pox. 124 under treatment. 6 under observation (last week 133 and 2 respectively); scarlet fever, 1180; diphtheria. 1451; enteric fever, 8; measles, 756; whooping-cough. 330; puerperal fever, 16 (plus 11 babies); encephalitis lethargica. 223; poliomyelitis. 3; "other diseases." 277. At St. Margaret's Hospital there were 25 babies (plus 14 mothers) with ophthalmia neonatorum.

Deaths.—In 117 great towns. including London, there was no death from small-pox or enteric fever. 40 (12) from measles. 5 (2) from scarlet fever. 41 (10) from whooping-cough. 34 (13) from diphtheria. 49 (17) from diarrhœa and enteritis under two years. and 392 (115) from influenza. The figures in parentheses are those for London itself.

The deaths from influenza show a slight drop from the figure of the two previous weeks. but the total for the year so far amounts to 1155. against 486 for the corresponding period of 1931. Of the great towns Birmingham stands highest this week with 24 deaths from influenza. followed by Manchester with 21. Bradford with 11. and Willesden with 10. Eleven deaths from measles were reported from Manchester. 4 from Stoke-on-Trent. Liverpool and Birmingham each reported 5 deaths from whooping-cough. Manchester and Newcastle each 3. Small-pox is mentioned as a cause of death in December last in a case assigned to Alfreton U.D., Derby.

The number of stillbirths notified during the week was 287 (corresponding to a rate of 43 per 1000 births), including 47 in London.

DEATH CLASSIFIED TO SMALL-POX.

THE fatal case assigned to Alfreton U.D., Derbyshire, was. Dr. Sydney O. Bingham tells us. of the ordinary mild type. It was that of a female infant, aged 6 months. who had just previously had an attack of chicken-pox. The cause of death was stated in the certificate as (1)(*a*) heart failure. (*b*) septicæmia. (*c*) cellulitis of leg; (2) small-pox. There was no post-mortem examination.

A CORRECTION.—In summarising the annual health report of Belfast in our issue of Jan. 9th (p. 105) we are sorry to have attributed to Dr. P. S. Walker some observations and opinions of Dr. Andrew Trimble. It was Dr. Trimble who pointed out that albumose or albumin is generally present in a positive sputum, and the particulars of pregnancy and tuberculosis were also contained in his report as chief tuberculosis officer.

DEATHS IN THE SERVICES.

Deputy Inspector General Samuel William Vasey. R.N. retd., a St. George's man who qualified in 1877. died at Teignmouth on Jan. 17th. aged 76. He entered the Navy as a surgeon in 1878 and a year later saw active service in the Zulu War, landing with the Naval Brigade of the *Boadicea* (Zulu Medal and Clasp): later he was present at the destruction of Batolonga *on the West Coast of Africa*; and during the Egyptian War of 1882 was surgeon of the *Seagull* (Egyptian Medal and Khedive's Bronze Star). In 1890 he became staff surgeon, and four years later fleet surgeon. In 1900 he served in the *Centurion*. the flagship of Vice-Admiral Sir Edward Seymour during the China operations, and after being appointed to the *Defiance*, the torpedo school ship at Devonport, retired in 1909.

being excluded for seven years. In the autumn of 1931 dental treatment of pregnant and nursing mothers and young children will be undertaken. Existing isolation hospitals will be used for the present, but the county council will insist on the pooling of resources and interchangeability of patients, so that accommodation may be found for the rarer infectious diseases, and that the occurrence of two cases of small-pox in different districts will not entail the opening of two small-pox hospitals.

Norfolk.

Dr. T. Ruddock-West records considerable progress during the last five years. Housing conditions have improved; more parishes have been provided with district nurses; practically the whole county has been covered for health visiting purposes, and dental treatment has been extended to necessitous expectant and nursing mothers. On the passing of the Local Government Act the county council decided that the public health committee with added members should also function as the public assistance committee. The new committee is styled the public health and assistance committee, and has subcommittees to deal with the various departments, with the exception of school medical inspection and treatment. The 14 transferred public assistance institutions are all of the mixed type. Arrangements are on foot to adapt and use the Heckingham institution for mental defectives and to transfer the cases of senile dementia to the Swainsthorpe institution in order to relieve the mental hospital.

The hospital accommodation in the county for medical and surgical cases appears to be adequate except for cases of surgical and advanced pulmonary tuberculosis. Since Stanninghall Colony (45 beds) was transferred to the council, it has been proposed to provide accommodation there for tuberculous and non-tuberculous crippling defects. Isolation accommodation both for infectious diseases and small-pox is inadequate, and the county council has approved the principle of a central hospital for those areas with no adequate provision, but owing to financial stringency no further action is to be taken at present. Plumstead Hall has 70 beds for mental defectives, and a scheme has been approved for its extension to form a 300-bed colony with service buildings for 500 patients.

All the urban districts except Wells have a piped water-supply. In Wells itself 55 houses have a piped supply but the remainder draw their supply from some 350 shallow wells, mostly liable to serious contamination. Outside the towns most of the water is obtained from shallow wells liable to pollution.

Many of the houses occupied by agricultural labourers and people in similar circumstances are poor in fabric and accommodation and cannot be considered in any way as reasonably fit. The agricultural labourer with 30*s.* a week cannot pay more than 4*s.* in rental. A table is included in the report showing the housing activities of the district councils, from which it appears that certain councils have been able to let houses at a rental of from 2*s.* 6*d.* to 3*s.* per week, inclusive of rates. Dr. Ruddock-West points out that if a large family occupies a condemned house, a special grant for rehousing them is available under Section 26 of the Housing Act, 1930. Some districts have used the Housing (R.W.) Act with satisfaction, while others have neglected it.

East Suffolk.

Dr. B. Wood-White shows that the district nursing associations have increased in number from 36 in 1921 to 70 in 1930. Of 320 parishes, 49 lack the services of a district nurse. From the point of view of public health administration, the provision of a general nursing service in urban and rural areas is of primary importance, and Dr. Wood-White thinks it is the right policy for the council to employ the district nurses as health visitors, in order that district nursing associations may ultimately cover the whole of the county. Some of the district nurses, however, have not had a general hospital training, and the experience and knowledge are not equal to those of a whole-time health visitor. Dr. Wood-White was unfortunately ill for five months during 1930, and his comments on the transferred medical services and institutions are not therefore available. He has much to say, however, as to the transferred Children Act, 1908. During the last quarter of the year the health visitors and district nurses supervised all nurse-children. The supervision age should, he thinks, be extended from 7 to 15 years. He regards lump sum payments as on the same footing as insurance policies. The arrangements for getting information from the foster-mother he finds inadequate. He cites a bad case of neglect, which came before a lenient bench. If, however, he had removed all the children to a place of safety, no bench of magistrates could have ordered the children to be taken back until the house was fit for their reception. Everyone will agree with Dr. Wood-White that the foster-mothers and their homes should be registered before any child is received.

In the towns of Eye, Framlingham, Needham Market, and Wickham Market there is no constant and pure water-supply, and in most of the rural districts a constant and pure supply of water is a rarity. Although the rural population drinks water that is polluted to some extent from time to time, Dr. Wood-White has not come across an outbreak of water-borne disease during his eight years' experience.

There is no tuberculosis dispensary in East Suffolk; patients are visited systematically at their own homes by the tuberculosis officers. There is, however an examination centre at Lowestoft (population 44,0 which is apparently not much used, and Dr. Wood White gives his reasons for thinking it would impracticable to set up an examination centre any other place.

Breconshire.

Dr. Herbert Davies says four poor-law institutic were transferred to the council and that one of th has since been closed, the inmates being moved one of the others. The beds available are 43 for m 42 for women, and 19 for children. The me hospital at Talgarth, with accommodation for 481 used jointly with the counties of Montgomery Radnor. Health visiting and school nursing carried out by four whole-time visitors, and the nurse-midwives of the local nursing associati which are subsidised according to the work d There are 79 practising midwives, 71 trained eight "bona fide." The midwives attended 827 o 932 live births and 43 stillbirths. They sent medical help in 204 of their cases. There ar maternity and child welfare centres, conducted b local nursing associations. The centres receive g and are attended by the assistant medical offic health, Dr. Winifred E. Probert. No action h yet been taken with regard to antenatal centres.

Dumfriesshire.

Dr. John Ritchie, referring to the high mat mortality (which compares with a rate of 7·0 f Scotland), expresses his conviction that this could be reduced if adequate prenatal superv were possible. It is comparatively easy to pr antenatal clinics in towns, but these have no pl rural administration with a widely scattered p tion, and the only promising scheme must be on the local practitioners and district nurses.

Water-supply is the most difficult problem the county and governs the question of house sion. A number of water schemes have bee forward recently and all given up on account cost. Dr. Ritchie suggests that the provisi gravitation water on a large scale must be a n for earnest consideration. There are several where reservoirs could be constructed to serv whole county, but the vast cost of distribut the obstacle, which the Town and Country Pla Bill may help to remove.

ng infectious diseases the event of the year water-borne epidemic of enteric fever at cham. The cases of enteric in the county the last four years numbered 2, 3, 3, and 5. 30 they rose in number to 70. In the early f the year there were three cases, and in the hree weeks of September, 23, 31, and 6 cases removed to hospital. Investigation showed vater was the only common factor, and later he pipes leading from the springs to one of the had faulty joints close to a land drain. One of ur farm servants was found to be a carrier. The r has worked in this area for more than three but the chain of circumstances favourable to a -borne epidemic had evidently not occurred , and on this occasion the water was probably infective for a few days between August 10th 4th. There were few secondary cases, which is eat contrast with the year 1895, when the cation reached a similar figure at a period when id was endemic.

o poor-houses, with 27 beds for the sick, transferred to the council under the Local rnment Act. Dr. Ritchie puts forward an ctive scheme for improving the hospital service he county. There are at present four small tion hospitals. He suggests that of these, maben should be slightly enlarged and carry all the isolation work. There would then be lable 74 beds in three modern well-constructed dings, which could be easily converted into cottage itals and used as annexes of the four voluntary ral hospitals, thus providing for convalescence abolishing waiting-lists.

Guernsey.

r. H. D. Bishop says that the births during the t thirty years of the century numbered 26,919, the maternal deaths in childbirth 55, giving a of 2·04 per 1000 births. The deaths from erculosis in 1930 were 36, of which 35 were due to hisis and one to tuberculous meningitis. The gle death from non-pulmonary tuberculosis is eresting on account of the claimed absence of the vine bacillus. Dr. Bishop complains that lmonary tuberculosis is only sent to the sanatorium an advanced stage; he would like the other spitals in the Islands to make greater provision the isolation of advanced cases. His suggestion at the poor-law board should be renamed the mmittee for public assistance, and cease to restrict s hospital provision to paupers, may be helpful. he "homes for workers" committee has completed s housing scheme, and now lends money at a low te of interest to persons who wish to build small ouses for themselves. The chief housing need now, ys Dr. Bishop, is for cheap flats for the small umber of families who are really undesirable tenants. sum of money is voted every year for the treatment of mental defectives, and occasionally cases fter a very long delay are sent to English institutions. r. Bishop recommends that the Channel Islands hould establish a joint institution, with facilities or grading and education. He also advocates the ormation of a cancer care committee to undertake ublicity work and render assistance to sufferers.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JAN. 23RD, 1932.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 55 (last week 68); scarlet fever, 1502; diphtheria, 946; enteric fever, 22; pneumonia, 1786; puerperal fever, 46; puerperal pyrexia, 108; cerebro-spinal fever, 57; acute poliomyelitis, 4; acute polio-encephalitis, 1; encephalitis lethargica, 16; continued fever, 1; dysentery, 17; ophthalmia neonatorum, 103. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Jan. 26th–27th was as follows: Small-pox, 124 under treatment, 6 under observation (last week 133 and 2 respectively); scarlet fever, 1180; diphtheria, 1151; enteric fever, 8; measles, 756; whooping-cough, 330; puerperal fever, 16 (plus 11 babies); encephalitis lethargica, 223; poliomyelitis, 3; "other diseases," 277. At St. Margaret's Hospital there were 25 babies (plus 14 mothers) with ophthalmia neonatorum.

Deaths.—In 117 great towns, including London, there was no death from small-pox or enteric fever, 40 (12) from measles, 5 (2) from scarlet fever, 41 (10) from whooping-cough, 34 (13) from diphtheria, 49 (17) from diarrhœa and enteritis under two years, and 392 (115) from influenza. The figures in parentheses are those for London itself.

The deaths from influenza show a slight drop from the figure of the two previous weeks, but the total for the year so far amounts to 1155, against 486 for the corresponding period of 1931. Of the great towns Birmingham stands highest this week with 21 deaths from influenza, followed by Manchester with 21, Bradford with 11, and Willesden with 10. Eleven deaths from measles were reported from Manchester, 4 from Stoke-on-Trent. Liverpool and Birmingham each reported 5 deaths from whooping-cough, Manchester and Newcastle each 3. Small-pox is mentioned as a cause of death in December last in a case assigned to Alfreton U.D., Derby.

The number of stillbirths notified during the week was 287 (corresponding to a rate of 43 per 1000 births), including 47 in London.

DEATH CLASSIFIED TO SMALL-POX.

THE fatal case assigned to Alfreton U.D., Derbyshire, was, Dr. Sydney O. Bingham tells us, of the ordinary mild type. It was that of a female infant, aged 6 months, who had just previously had an attack of chicken-pox. The cause of death was stated in the certificate as (1)(*a*) heart failure, (*b*) septicæmia, (*c*) cellulitis of leg; (2) small-pox. There was no post-mortem examination.

A CORRECTION.—In summarising the annual health report of Belfast in our issue of Jan. 9th (p. 105) we are sorry to have attributed to Dr. P. S. Walker some observations and opinions of Dr. Andrew Trimble. It was Dr. Trimble who pointed out that albumose or albumin is generally present in a positive sputum, and the particulars of pregnancy and tuberculosis were also contained in his report as chief tuberculosis officer.

East Suffolk.

Dr. B. Wood-White shows that the district nursing associations have increased in number from 36 in 1921 to 70 in 1930. Of 320 parishes, 49 lack the services of a district nurse. From the point of view of public health administration, the provision of a general nursing service in urban and rural areas is of primary importance, and Dr. Wood-White thinks it is the right policy for the council to employ the district nurses as health visitors, in order that district nursing associations may ultimately cover the whole of the county. Some of the district nurses, however, have not had a general hospital training, and their experience and knowledge are not equal to those of a whole-time health visitor. Dr. Wood-White was unfortunately ill for five months during 1930, and his comments on the transferred medical services and institutions are not therefore available. He has much to say, however, as to the transferred Children Act, 1908. During the last quarter of the year the health visitors and district nurses supervised 357 nurse-children. The supervision age should, he thinks, be extended from 7 to 15 years. He regards lump sum payments as on the same footing as insurance policies. The arrangements for getting information from the foster-mother he finds inadequate. He cites a bad case of neglect, which came before a lenient bench. If, however, he had removed all the children to a place of safety, no bench of magistrates could have ordered the children to be taken back until the house was fit for their reception. Everyone will agree with Dr. Wood-White that the foster-mothers and their homes should be registered before any child is received.

In the towns of Eye, Framlingham, Needham Market, and Wickham Market there is no constant and pure water-supply, and in most of the rural districts a constant and pure supply of water is a rarity. Although the rural population drinks water that is polluted to some extent from time to time, Dr. Wood-White has not come across an outbreak of water-borne disease during his eight years' experience.

There is no tuberculosis dispensary in East Suffolk; patients are visited systematically at their own homes by the tuberculosis officers. There is, however, an examination centre at Lowestoft (population 44,000) which is apparently not much used, and Dr. Wood-White gives his reasons for thinking it would be impracticable to set up an examination centre in any other place.

Breconshire.

Dr. Herbert Davies says four poor-law institutions were transferred to the council and that one of them has since been closed, the inmates being moved to one of the others. The beds available are 43 for men, 42 for women, and 19 for children. The mental hospital at Talgarth, with accommodation for 481, is used jointly with the counties of Montgomery and Radnor. Health visiting and school nursing is carried out by four whole-time visitors, and the 19 nurse-midwives of the local nursing associations, which are subsidised according to the work done. There are 79 practising midwives, 71 trained and eight "bona fide." The midwives attended 827 of the 932 live births and 43 stillbirths. They sent for medical help in 204 of their cases. There are 12 maternity and child welfare centres, conducted by the local nursing associations. The centres receive grants and are attended by the assistant medical officer of health, Dr. Winifred E. Probert. No action has as yet been taken with regard to antenatal centres.

Dumfriesshire.

Dr. John Ritchie, referring to the high maternal mortality (which compares with a rate of 7·0 for all Scotland), expresses his conviction that this rate could be reduced if adequate prenatal supervision were possible. It is comparatively easy to provide antenatal clinics in towns, but these have no place in rural administration with a widely scattered population, and the only promising scheme must be based on the local practitioners and district nurses.

Water-supply is the most difficult problem before the county and governs the question of house provision. A number of water schemes have been put forward recently and all given up on account of the cost. Dr. Ritchie suggests that the provision of gravitation water on a large scale must be a matter for earnest consideration. There are several places where reservoirs could be constructed to serve the whole county, but the vast cost of distribution is the obstacle, which the Town and Country Planning Bill may help to remove.

Among infectious diseases the event of the year was a water-borne epidemic of enteric fever at Ecclefecham. The cases of enteric in the county during the last four years numbered 2, 3, 3, and 5. In 1930 they rose in number to 70. In the early part of the year there were three cases, and in the first three weeks of September, 23, 31, and 6 cases were removed to hospital. Investigation showed that water was the only common factor, and later that the pipes leading from the springs to one of the tanks had faulty joints close to a land drain. One of the four farm servants was found to be a carrier. The carrier has worked in this area for more than three years, but the chain of circumstances favourable to a water-borne epidemic had evidently not occurred before, and on this occasion the water was probably only infective for a few days between August 10th and 14th. There were few secondary cases, which is in great contrast with the year 1895, when the notification reached a similar figure at a period when typhoid was endemic.

Two poor-houses, with 27 beds for the sick, were transferred to the council under the Local Government Act. Dr. Ritchie puts forward an attractive scheme for improving the hospital service of the county. There are at present four small isolation hospitals. He suggests that of these, Lochmaben should be slightly enlarged and carry out all the isolation work. There would then be available 74 beds in three modern well-constructed buildings, which could be easily converted into cottage hospitals and used as annexes of the four voluntary general hospitals, thus providing for convalescence and abolishing waiting-lists.

Guernsey.

Dr. H. D. Bishop says that the births during the first thirty years of the century numbered 26,919, and the maternal deaths in childbirth 55, giving a rate of 2·04 per 1000 births. The deaths from tuberculosis in 1930 were 36, of which 35 were due to phthisis and one to tuberculous meningitis. The single death from non-pulmonary tuberculosis is interesting on account of the claimed absence of the bovine bacillus. Dr. Bishop complains that pulmonary tuberculosis is only sent to the sanatorium at an advanced stage; he would like the other hospitals in the Islands to make greater provision for the isolation of advanced cases. His suggestion that the poor-law board should be renamed the committee for public assistance, and cease to restrict its hospital provision to paupers, may be helpful. The "homes for workers" committee has completed its housing scheme, and now lends money at a low rate of interest to persons who wish to build small houses for themselves. The chief housing need now, says Dr. Bishop, is for cheap flats for the small number of families who are really undesirable tenants. A sum of money is voted every year for the treatment of mental defectives, and occasionally cases after a very long delay are sent to English institutions. Dr. Bishop recommends that the Channel Islands should establish a joint institution, with facilities for grading and education. He also advocates the formation of a cancer care committee to undertake publicity work and render assistance to sufferers.

The hospital accommodation in the county for medical and surgical cases appears to be adequate except for cases of surgical and advanced pulmonary tuberculosis. Since Stanninghall Colony (45 beds) was transferred to the council, it has been proposed to provide accommodation there for tuberculous and non-tuberculous crippling defects. Isolation accommodation both for infectious diseases and small-pox is inadequate, and the county council has approved the principle of a central hospital for those areas with no adequate provision, but owing to financial stringency no further action is to be taken at present. Plumstead Hall has 70 beds for mental defectives, and a scheme has been approved for its extension to form a 300-bed colony with service buildings for 500 patients.

All the urban districts except Wells have a piped water-supply. In Wells itself 55 houses have a piped supply but the remainder draw their supply from some 350 shallow wells, mostly liable to serious contamination. Outside the towns most of the water is obtained from shallow wells liable to pollution.

Many of the houses occupied by agricultural labourers and people in similar circumstances are poor in fabric and accommodation and cannot be considered in any way as reasonably fit. The agricultural labourer with 30*s.* a week cannot pay more than 4*s.* in rental. A table is included in the report showing the housing activities of the district councils, from which it appears that certain councils have been able to let houses at a rental of from 2*s.* 6*d.* to 3*s.* per week, inclusive of rates. Dr. Ruddock-West points out that if a large family occupies a condemned house, a special grant for rehousing them is available under Section 26 of the Housing Act, 1930. Some districts have used the Housing (R.W.) Act with satisfaction, while others have neglected it.

East Suffolk.

Dr. B. Wood-White shows that the district nursing associations have increased in number from 36 in 1921 to 70 in 1930. Of 320 parishes, 49 lack the services of a district nurse. From the point of view of public health administration, the provision of a general nursing service in urban and rural areas is of primary importance, and Dr. Wood-White thinks it is the right policy for the council to employ the district nurses as health visitors, in order that district nursing associations may ultimately cover the whole of the county. Some of the district nurses, however, have not had a general hospital training, and their experience and knowledge are not equal to those of a whole-time health visitor. Dr. Wood-White was unfortunately ill for five months during 1930, and his comments on the transferred medical services and institutions are not therefore available. He has much to say, however, as to the transferred Children Act, 1908. During the last quarter of the year the health visitors and district nurses supervised 357 nurse-children. The supervision age should, he thinks, be extended from 7 to 15 years. He regards lump sum payments as on the same footing as insurance policies. The arrangements for getting information from the foster-mother he finds inadequate. He cites a bad case of neglect, which came before a lenient bench. If, however, he had removed all the children to a place of safety, no bench of magistrates could have ordered the children to be taken back until the house was fit for their reception. Everyone will agree with Dr. Wood-White that the foster-mothers and their homes should be registered before any child is received.

In the towns of Eye, Framlingham, Needham Market, and Wickham Market there is no constant and pure water-supply, and in most of the rural districts a constant and pure supply of water is a rarity. Although the rural population drinks water that is polluted to some extent from time to time, Dr. Wood-White has not come across an outbreak of water-borne disease during his eight years' experience.

There is no tuberculosis dispensary in East Suffolk; patients are visited systematically at their own homes by the tuberculosis officers. There is, however, an examination centre at Lowestoft (population 44,000) which is apparently not much used, and Dr. Wood-White gives his reasons for thinking it would be impracticable to set up an examination centre in any other place.

Breconshire.

Dr. Herbert Davies says four poor-law institutions were transferred to the council and that one of them has since been closed, the inmates being moved to one of the others. The beds available are 43 for men, 42 for women, and 19 for children. The mental hospital at Talgarth, with accommodation for 481, is used jointly with the counties of Montgomery and Radnor. Health visiting and school nursing is carried out by four whole-time visitors, and the 19 nurse-midwives of the local nursing associations, which are subsidised according to the work done. There are 79 practising midwives, 71 trained and eight "bona fide." The midwives attended 827 of the 932 live births and 43 stillbirths. They sent for medical help in 204 of their cases. There are 12 maternity and child welfare centres, conducted by the local nursing associations. The centres receive grants and are attended by the assistant medical officer of health, Dr. Winifred E. Probert. No action has as yet been taken with regard to antenatal centres.

Dumfriesshire.

Dr. John Ritchie, referring to the high maternal mortality (which compares with a rate of 7·0 for all Scotland), expresses his conviction that this rate could be reduced if adequate prenatal supervision were possible. It is comparatively easy to provide antenatal clinics in towns, but these have no place in rural administration with a widely scattered population, and the only promising scheme must be based on the local practitioners and district nurses.

Water-supply is the most difficult problem before the county and governs the question of house provision. A number of water schemes have been put forward recently and all given up on account of the cost. Dr. Ritchie suggests that the provision of gravitation water on a large scale must be a matter for earnest consideration. There are several places where reservoirs could be constructed to serve the whole county, but the vast cost of distribution is the obstacle, which the Town and Country Planning Bill may help to remove.

Among infectious diseases the event of the year was a water-borne epidemic of enteric fever at Ecclefecham. The cases of enteric in the county during the last four years numbered 2, 3, 3, and 5. In 1930 they rose in number to 70. In the early part of the year there were three cases, and in the first three weeks of September, 23, 31, and 6 cases were removed to hospital. Investigation showed that water was the only common factor, and later that the pipes leading from the springs to one of the tanks had faulty joints close to a land drain. One of the four farm servants was found to be a carrier. The carrier has worked in this area for more than three years, but the chain of circumstances favourable to a water-borne epidemic had evidently not occurred before, and on this occasion the water was probably only infective for a few days between August 10th and 14th. There were few secondary cases, which is in great contrast with the year 1895, when the notification reached a similar figure at a period when typhoid was endemic.

Two poor-houses, with 27 beds for the sick, were transferred to the council under the Local Government Act. Dr. Ritchie puts forward an attractive scheme for improving the hospital service of the county. There are at present four small isolation hospitals. He suggests that of these, Lochmaben should be slightly enlarged and carry out all the isolation work. There would then be available 74 beds in three modern well-constructed buildings, which could be easily converted into cottage hospitals and used as annexes of the four voluntary general hospitals, thus providing for convalescence and abolishing waiting-lists.

Guernsey.

Dr. H. D. Bishop says that the births during the first thirty years of the century numbered 26,919, and the maternal deaths in childbirth 55, giving a rate of 2·04 per 1000 births. The deaths from tuberculosis in 1930 were 36, of which 35 were due to phthisis and one to tuberculous meningitis. The single death from non-pulmonary tuberculosis is interesting on account of the claimed absence of the bovine bacillus. Dr. Bishop complains that pulmonary tuberculosis is only sent to the sanatorium at an advanced stage; he would like the other hospitals in the Islands to make greater provision for the isolation of advanced cases. His suggestion that the poor-law board should be renamed the committee for public assistance, and cease to restrict its hospital provision to paupers, may be helpful. The "homes for workers" committee has completed its housing scheme, and now lends money at a low rate of interest to persons who wish to build small houses for themselves. The chief housing need now, says Dr. Bishop, is for cheap flats for the small number of families who are really undesirable tenants. A sum of money is voted every year for the treatment of mental defectives, and occasionally cases after a very long delay are sent to English institutions. Dr. Bishop recommends that the Channel Islands should establish a joint institution, with facilities for grading and education. He also advocates the formation of a cancer care committee to undertake publicity work and render assistance to sufferers.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JAN. 23RD, 1932.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 55 (last week 68); scarlet fever, 1502; diphtheria, 946; enteric fever, 22; pneumonia, 1786; puerperal fever, 46; puerperal pyrexia, 108; cerebro-spinal fever, 57; acute poliomyelitis, 4; acute polio-encephalitis, 1; encephalitis lethargica, 16; continued fever, 1; dysentery, 17; ophthalmia neonatorum, 103. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Jan. 26th–27th was as follows: Small-pox, 124 under treatment, 6 under observation (last week 133 and 2 respectively); scarlet fever, 1180; diphtheria, 1451; enteric fever, 8; measles, 756; whooping-cough, 330; puerperal fever, 16 (plus 11 babies); encephalitis lethargica, 223; poliomyelitis, 3; "other diseases," 277. At St. Margaret's Hospital there were 25 babies (plus 11 mothers) with ophthalmia neonatorum.

Deaths.—In 117 great towns, including London, there was no death from small-pox or enteric fever, 40 (12) from measles, 5 (2) from scarlet fever, 41 (10) from whooping-cough, 34 (13) from diphtheria, 49 (17) from diarrhœa and enteritis under two years, and 392 (115) from influenza. The figures in parentheses are those for London itself.

The deaths from influenza show a slight drop from the figure of the two previous weeks, but the total for the year so far amounts to 1155, against 486 for the corresponding period of 1931. Of the great towns Birmingham stands highest this week with 24 deaths from influenza, followed by Manchester with 21, Bradford with 11, and Willesden with 10. Eleven deaths from measles were reported from Manchester, 4 from Stoke-on-Trent. Liverpool and Birmingham each reported 5 deaths from whooping-cough, Manchester and Newcastle each 3. Small-pox is mentioned as a cause of death in December last in a case assigned to Alfreton U.D., Derby.

The number of stillbirths notified during the week was 287 (corresponding to a rate of 43 per 1000 births), including 47 in London.

DEATH CLASSIFIED TO SMALL-POX.

THE fatal case assigned to Alfreton U.D., Derbyshire, was, Dr. Sydney O. Bingham tells us, of the ordinary mild type. It was that of a female infant, aged 6 months, who had just previously had an attack of chicken-pox. The cause of death was stated in the certificate as (1)(*a*) heart failure, (*b*) septicæmia, (*c*) cellulitis of leg; (2) small-pox. There was no post-mortem examination.

A CORRECTION.—In summarising the annual health report of Belfast in our issue of Jan. 9th (p. 105) we are sorry to have attributed to Dr. P. S. Walker some observations and opinions of Dr. Andrew Trimble. It was Dr. Trimble who pointed out that albumose or albumin is generally present in a positive sputum, and the particulars of pregnancy and tuberculosis were also contained in his report as chief tuberculosis officer.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

F. W. A. Fosbery to be Surg. Lt.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Lt. E. F. St.J. Lyburn to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS.

Majs. W. B. Stevenson and C. J. H. Little retire on retd. pay.

Lts. H. W. Daukes, A. T. H. Marsden, and L. R. H. Keatinge *to be Capts.*

ROYAL AIR FORCE.

Flight Lt. J. W. Harper relinquishes his commission on completion of service and is permitted to retain his rank.

AUXILIARY AIR FORCE.

No. 600 (*City of London*) (*Bomber*) *Squadron.*—H. W. Walter is granted a commission as a Flying Officer.

DEATHS IN THE SERVICES.

Deputy Inspector General Samuel William Vasey, R.N. retd., a St. George's man who qualified in 1877, died at Teignmouth on Jan. 17th, aged 76. He entered the Navy as a surgeon in 1878 and a year later saw active service in the Zulu War, landing with the Naval Brigade of the *Boadicea* (Zulu Medal and Clasp); later he was present at the destruction of Batolonga on the West Coast of Africa; and during the Egyptian War of 1882 was surgeon of the *Seagull* (Egyptian Medal and Khedive's Bronze Star). In 1890 he became staff surgeon, and four years later fleet surgeon. In 1900 he served in the *Centurion*, the flagship of Vice-Admiral Sir Edward Seymour during the China operations, and after being appointed to the *Defiance*, the torpedo school ship at Devonport, retired in 1909.

CORRESPONDENCE

ANDREW BALFOUR MEMORIAL.

To the Editor of THE LANCET.

SIR,—It has been decided to found a memorial to Sir Andrew Balfour, who died in January, 1931, shortly after the opening of the London School of Hygiene and Tropical Medicine, of which he was the first Director. When funds are available it is intended to place a simple and inexpensive monument in the school, and with the remainder of the sum received to establish an Andrew Balfour Memorial Fund for helping students, preferably from overseas, to pursue courses of study at the school. We feel that Balfour's many friends all over the world would not wish to miss the opportunity of contributing to such a memorial, and we are confident that even considerations of hard times, heavy taxation, or other depressing circumstances will not deter those friends from helping to build up a fund of worthy proportions as a permanent memorial to a magnificent career.

While it is hoped that all who can do so will send a donation in the near future, it is not proposed to limit the period during which the fund will remain open, and promises of donations or bequests will be gategully acknowledged. Contributions should be sent to the Honorary Treasurer, Andrew Balfour Memorial Fund, London School of Hygiene and Tropical Medicine, Keppel-street, W.C.1.

We are, Sir, yours faithfully,

JAMES CRICHTON-BROWNE,
JAMES CURRIE,
M. H. G. FELL,
W. H. N. GOSCHEN,
D. LYALL GRANT,
W. W. JAMESON,

C. M. WENYON,
REGINALD WINGATE.

January, 1932.

THE CARDIAC CYCLE.

To the Editor of THE LANCET.

SIR,—Your reviewer states accurately the conclusion I had reached concerning the genesis of the pulse-wave—viz., that it resulted from the impact on the aortic valve of the rising tension developed within the ventricle during the isometric phase of the systole; but he calls this a "hypothesis." I prefer to call it a deduction arrived at by an argument based upon a postulate which he entirely ignores, namely, that the laws which govern the operation of matter in the outside world continue to rule unchanged after the incorporation of such matter within the living organism. Thus I have urged that Newton's laws of motion must hold good in Harvey's circulation.

As the reviewer states the case with this postulate left out, my deduction is in the air and stands as a mere arbitrary statement without authority, since I do not bring any experimental evidence. But is there any experimental evidence on the time relations of the conclusion of the isometric phase and the commencement of the expulsion phase? He says my conclusion (his hypothesis) "is entirely incompatible with the known experimental facts," but he does not cite these "facts." What can I say more? He has left undiscussed the postulate which is stressed in the opening words of my argument; which, so far as I am aware, does bring forward a new method of approach regarding the problem of the circulation.

I share his desire for experimental confirmation of my contentions, but think they may be very difficult, since they will have to deal with such minute time-quantities, 1/100th of a second or less. Besides, experiment is not without its dangers—for how many years did not the development of a negative pressure within the ventricle, during diastole, continue to be taught, because Newton's law of inertia was not made sufficient allowance for until the inertia of the lever was got rid of by using the beam of light?

I am, Sir, yours faithfully,
HARRINGTON SAINSBURY.

Hampstead, N.W., Jan. 28th, 1932.

TREATMENT OF SUBACUTE COMBINED DEGENERATION OF THE CORD.

To the Editor of THE LANCET.

SIR,—I have read with great interest Dr. Sargant's paper in your last issue on the treatment of subacute combined degeneration with massive doses of iron. The striking results obtained certainly merit prolonged further trial. There are, however, two points which call for some remark.

1. The author states that "in the treatment of subacute combined degeneration of the cord, liver therapy is usually of little or no use." The results obtained in a large series of cases investigated in Newcastle,[1] Toronto,[2] Baltimore,[3] and Boston [4] have shown that whole liver, in adequate amounts, is effective in the majority of cases. But the amount of liver required for producing neurological benefit is frequently much more than that required for the maintenance of the red blood-cell level. Indeed, many cases require from 240–480 g. of whole liver daily. In a total of over 150 liver-treated cases of subacute combined degeneration at the Massachusetts General Hospital,[4] Boston City Hospital, and Royal Victoria Infirmary,[1] it was possible to find less than ten who had failed to respond when the dosage had been 240–480 g. for four months or more. The majority had benefited even with doses as low as 960 g. a week. Those who had died or failed to improve, and those in whom neurological symptoms developed for the first time during treatment, had taken liver in small amounts, or irregularly, often in the form of liver extract; in many of these septic complications were present also.

2. The statement that "in cases of subacute combined degeneration, the blood picture is rarely that of a typical pernicious anæmia" has already been criticised in your annotation. Experience has shown that the anæmia which is almost invariably present at some period of the disease is typically "pernicious" in type, both morphologically and in its response to treatment. It is noteworthy that three out of four of Dr. Sargant's cases had a colour-index of 1·0 or over.

With regard to the possible nature of the factor responsible for the neurological improvement (p. 255), it may be noted that it is presumably a substance present in both liver and brain in approximately equal proportions, with perhaps a slightly greater concentration in brain tissue. As already mentioned this would virtually exclude the so-called anti-anæmic factor, and also vitamin A. In my paper further discussion of the nature of the effective substance was not entered into, as I thought this would be better postponed until further evidence is available as to the relative potency of brain, liver, and other substances for producing neurological benefit.

[3] Baker, B. M., Bordley, J., iii., and Longcope, W. T.: Minnesota Med., 1930, xiii., 815.

[4] Suzman, M. M.: Trans. Amer. Neurolog. Assoc., 1931.

The statement attributed to me in the annotation that I concluded "that the effect of brain upon the nervous system is markedly greater than that of liver," requires moderation, and differs in degree from the deductions I actually made in my paper.

I am, Sir, yours faithfully,

Newcastle-on-Tyne, Jan. 30th, 1932. C. C. UNGLEY.

To the Editor of THE LANCET

SIR,—While Dr. Sargant's results in the treatment of four cases of subacute combined degeneration of the cord with large doses of iron are of interest and importance, his summary dismissal of liver treatment as "usually of little or no use" should not I think pass unchallenged. Since the publication in 1929 by Ungley and Suzman of their observations on 61 cases seen at the Royal Victoria Infirmary, Newcastle, during four years, further experience has not led me, personally, to doubt the general truth of their conclusion that whole liver in adequate amount has a markedly beneficial effect on this condition. Much longer time is required to produce amelioration of the nervous symptoms and signs than to render the blood count normal, and relapse rapidly follows cessation of liver feeding. While I have seen remarkable improvement in advanced and bedridden cases, I think it of much greater importance to detect the cases early as there is then a good prospect not only of arrest of the process, but of considerable retrogression of the symptoms and signs.

Insistent subjective symptoms, especially tingling in hands and feet, arising in people at or over middle age, are highly suggestive, though not sufficient for the diagnosis of subacute combined degeneration, even if associated with loss of the deep reflexes; but if to such paræsthesiæ is added definite ataxia, even though slight, the diagnosis appears to me fully justified, always provided early or manifest signs of pernicious anæmia can be detected. Complete achlorhydria is a necessary part of the picture.

Advanced cases, cases complicated by severe sepsis, and I think also some cases which relapse by reason of stopping liver, may show little or no response, and there is no doubt that some cases in whom none of these factors is present fail to respond for no known reason. My experience, however, supports the claim of Ungley and Suzman that the last group is a small one.

I am, Sir, yours faithfully,

Newcastle-on-Tyne, Jan. 30th, 1932. F. J. NATTRASS.

THE SPAHLINGER VACCINES.

To the Editor of THE LANCET.

SIR,—I have the honour to enclose herewith a statement of my method for the preparation of antigens, with detailed reference to tuberculosis. With this *formula*, I have made bovine antituberculous vaccines for a number of years, and a series of tests has been carried out with very successful results. The vaccine is absolutely free from living micro-organisms and has been used for human antituberculous vaccination by distinguished medical men. But only large and extended statistics can provide evidence as to the degree and duration of the immunisation in human beings.

One of the aims of my researches has been to elucidate the mechanism of antibody production. It is my intention to communicate the results of these researches before a scientific body at an early date. I trust that you will accord me your valuable coöperation by publishing my formula for the information of your medical and scientific readers, so that this method can, without delay, be explored in as many other fields of research as possible.

I am, Sir, yours faithfully,

H. SPAHLINGER.

Institut Bactériothérapique, Carouge, Genève,

⁂ The statement referred to appears on p. 309.—ED. L.

TUBAL PREGNANCY.

To the Editor of THE LANCET.

SIR,—Mr. W. E. Tanner's account, in your issue of Jan. 16th, of an instance of Cullen's "umbilical sign" in a case of intraperitoneal bleeding at once attracted my attention. Ever since it was first described in 1920 or thereabouts, I have been on the look-out for it. In spite of likely opportunities I have not seen the condition nor do I know of any other reported instance. Indeed, doubt has been thrown upon its significance by E. A. Schumann, who records[1] a case in which there was "marked bluish discolouration about the umbilicus." This was thought to corroborate the diagnosis of ectopic pregnancy which had been based on a highly suggestive symptom-complex. However, at operation there was found: (1) normal uterine pregnancy, (2) bilateral acute salpingitis, (3) no blood in the peritoneal cavity. Therefore, he argued, the sign is not pathognomonic.

The possibility of the bruising being due to external manipulations applied to relieve pain has been suggested, but Mr. Tanner tells me that he has assured himself that nothing of the sort occurred in his case.

I am, Sir, yours faithfully,

Sheffield, Jan. 27th, 1932. MILES H. PHILLIPS.

To the Editor of THE LANCET.

SIR,—In my short letter published in your issue of Jan. 23rd, concerning Mr. Tanner's interesting report of a case of tubal pregnancy, in which he said "I cannot find a record of any similar case"—a very different statement from "it was rare" which is what, he now declares, was all he suggested—I pointed out that the sign of umbilical discolouration had been first described "in the United States many years ago." I had Cullen's name in mind, but, being, as I said in that letter, away from references when I wrote, I did not wish to commit myself further in regard to details, and I merely called Mr. Tanner's attention to the fact that the sign was "not unknown." I have seen it myself, and one of my assistants, to whom I have spoken, tells me he has seen it independently. I have, for a long time, referred to it when discussing with my students tubal gestation. However, this matter is no longer in doubt, and now that attention has been focused on it, we shall, perhaps, hear more about it in future.

With regard to the letter—an unhappy essay in respect of manners and material—of Mr. Aubrey Goodwin, whom I do not know personally, I can only say that I have never indulged in "post-prandial red herrings," nor is it a "fact," as Mr. Goodwin states, "that Prof. Blair Bell likes to feel that he is not as other gynæcologists"; the truth is rather that he wishes some other gynæcologists felt as he does about conservative gynæcological surgery. Clearly Mr. Goodwin has not read my address[1] on this subject. I daresay he would consider it waste of his valuable time to do so. Nevertheless, I can assure him that outside London, at any rate, there are gynæcologists in this country, as in America, who approach the treatment of tubal pregnancy with the same physiological reverence that I do. This is not to say that every tube can be saved: such a statement would be ridiculous; but it may safely be asserted that in at least 80 per cent. of all tubal pregnancies the tubes can be and should be conserved. It seemed to me that Mr. Tanner's case was one suitable for conservative measures, so I asked why a drastic—that is, eradicative—procedure had been practised.

---

[1] Amer. Jour. Obst. Gyn., 1923, vi., 632.

A considerable number of cases successfully treated on conservative lines could be collected in this country alone—patients who, as my own, have had children afterwards. In none of my patients so far as I know has ectopic pregnancy subsequently occurred. This question was raised when I first reported a case in 1922.[2] Recent inquiries have brought the information that this patient, hitherto nulliparous, has since had two healthy children.

Further, I may say that tubes treated conservatively by us are now subsequently tested by means of lipiodol injections. All my cases so examined, even those in which the condition has been of long standing, have shown patency with the possible exception of one. Further facts may be obtained from my address to which reference has been made.

I am sorry that any gynæcologist should find it necessary to ask me such elementary questions as those propounded by Mr. Goodwin. However, I suppose I must answer them or he will accuse me of evasion which is not one of my bad characteritics.

1. *Tubal pregnancy occurs more often in normal tubes than in abnormal.* So long ago as twenty-two years I wrote: "Formerly, it was supposed that inflammatory diseases of the tubes were the cause of tubal pregnancies, but it is now thought that the condition is more or less accidental and depends upon the situation of the ovum at the stage of development when the trophoblast is capable of producing implantation."[3] I have never had any reason to alter that view, indeed it has been confirmed. There is, of course, no doubt that anatomical anomalies produced by errors of development, neoplasms and infections may occasionally be the ætiological factors concerned, but they are, I believe, relatively uncommon. I cannot here discuss all the evidence that supports the view I have quoted—indeed, to do so can hardly be necessary to-day.

Conclusion.—It *is* sound surgery to conserve the tube, when there is no definite contra-indication to this procedure. It is unsound surgery—antiquated surgery—to do otherwise.

2. The guarantee for which Mr. Goodwin asks in his second question is given in our knowledge of physiological and pathological processes—namely, that as a rule the chorionic elements perish soon after the death of the embryo, and that chorion-epithelioma is as rare in the Fallopian tubes as it is in the uterus, and for the same reason.

3. No guarantee is required that the "large vessels ruptured in the tube wall, or even the raw edges will not continue to bleed . . ." for three reasons: first, bleeding has often ceased entirely; secondly, if it has not it can generally be controlled by simple surgical procedures; thirdly, in a few cases, as I have said, removal may be necessary—the number depending on the craftsmanship and vision of the surgeon.

In amplification of this last answer, I would point out that ampullary pregnancy is the commonest type of tubal gestation, and that a majority of these have aborted completely at the time of operation or have been converted into moles with no evidence of active hæmorrhage. I have removed quite large moles by salpingotomy, and one or two through the dilated abdominal ostium.

Mr. Tanner says nothing about active bleeding. Out of fairness to him I said "presumably" the tube contained a mole; but, frankly, the illustration is much more like that of the ampullary end of a tube from which complete abortion had occurred, and which required no more than suspension to the round ligament; but obviously I cannot speak definitely about this not having seen the specimen. Still there is nothing in the text to indicate anything to the contrary, and the simple procedure just mentioned would have saved the time which Mr. Tanner appears from his letter to have required for some reason not explained. He writes that removal was "the only quick and safe way of arresting hæmorrhage which had filled the abdomen with blood." However, if there were a mole still in the tube, salpingotomy or its removal through the abdominal ostium would have taken very little time. I have never seen the abdomen "full" of blood in this type of case, if in any. In this patient the history indicates that tubal abortion commenced on Oct. 17th and that there was pain and vomiting on Oct. 30th; but the evidence of discolouration shows that the hæmorrhage occurred at the earlier attack. Moreover, we are told the pulse was 72, the temperature was normal, and that she did not look anæmic at the time of operation. We may conclude, therefore, that hæmorrhage had ceased ten days previously to surgical intervention, and infer, I think, safely, as there is nothing in the text or illustration to contradict the inference, that the case was one of tubal abortion, and not of tubal rupture as stated by Mr. Tanner in the title of his paper.

In a large majority of all cases of tubal pregnancy implantation is in the ampulla, and abortion, not rupture, occurs; and after the initial hæmorrhage there is little to be feared from this complication. That Mr. Tanner is conservatively inclined is shown by his respect for the ovary of the same side. I cordially agree with Mr. Tanner in the hope that his patient will not have a tubal pregnancy in the remaining tube. It would be a calamity if she were to lose that too. I am sure Mr. Tanner merely performed the routine practice he has been taught and seen—as I did myself before 1922—without giving thought to the possibility of saving the tube. Nevertheless, we must all be very grateful to him for bringing to our notice an excellent example of Cullen's physical sign. I have fought for many years for conservation of ovarian tissue, and I have for some years tried to evoke a conservative physiological attitude in regard to these much maligned tubes. I hope Mr. Tanner will forgive my raising the point in connexion with his case. If we all sat down and thought and "felt" as others do there would be no progress.

I make no apology for the length of this letter, which does not exhaust all I might say in answer to the questions raised, for the matter is of some moment to many unfortunate young women.

I am, Sir, yours faithfully,

Liverpool, Jan. 29th, 1932. W. BLAIR BELL.

FILLING UP A DEATH CERTIFICATE.

To the Editor of THE LANCET.

SIR,—Dr. A. B. Dunne, in his letter to THE LANCET of to-day's date, complains of the manner in which the medical practitioner allocates the causes of death as between primary and secondary causes and proceeds to give a few instances of what he terms gross error that have come to his notice. He uses the terms "primary cause" and "secondary" in his examples. I should like to point out to him in the first place that the terms primary and secondary unfortunately do not appear on the Official Certificate of Death. If they did, fewer mistakes would be made.

In the second place, I should like to refer to his example No. 2 in which the primary cause appears as hæmatemesis and the secondary as cancer of the stomach. If Dr. Dunne will consult his book of "Forms for Medical Certificates of the Cause of Death" and study page vii., on which appear examples of how a death certificate is to be filled in, he will find example No. 4 which reads as follows :

Immediate cause	Hæmatemesis.
Morbid conditions, if any, giving rise to immediate cause (stated in order proceeding backwards from immediate cause)	Chronic gastric ulcer.

I would suggest that Dr. Dunne, instead of tilting against the medical practitioner, should turn his lance against the authority responsible for the present phraseology on the official forms of notification.

I am, Sir, yours faithfully,

Harley-street, W., Jan. 30th, 1932. C. E. LAKIN.

ERYTHROCYTE SEDIMENTATION TEST.

To the Editor of THE LANCET.

SIR,—The interesting and instructive letter on the above subject by Mr. J. E. R. McDonagh reminds me that about 40 years ago I pointed out that the precipitants of serum albumin in the urine were all dehydrants that removed the water of hydration from the large molecules of albumin, and the permanence of the precipitate depended on the amount of the water of hydration abstracted. Picric acid precipitates the albumin which again passes into solution on the addition of water. I am very glad that you have published his letter, as it has drawn my attention to what I have missed by not previously reading his three volumes on the Nature of Disease. I must now proceed at once with my own edification.

I am, Sir, yours faithfully,

Hindhead, Jan. 29th, 1932. JAMES BARR.

PS.—May I add that I was much interested by the article Massive Enlargement of the Breast, appearing in your current issue by Mr. H. H. Greenwood, as I have cured some such cases by large doses of iodine, and personally I have strong objections to unnecessary operations, whether for æsthetic or any other reason. The breasts should be suspended, but not compressed, so as to lessen all circulatory stagnation. I prescribe about 10 minims of either the English or French tincture of iodine in half a wineglass of milk, thrice daily after meals. If there be any deficiency in calcium it is well to add about grs. 2 of calcium iodide to each dose. The diet should be light and nutritious, not much carbohydrate or table salt. There is always a risk of large doses of iodine giving rise to hyperthyroidism, so the patient should be warned against such a possibility, and advised to pay an occasional visit to her medical attendant. If such an occurrence should occur it is easily remedied by stopping or lessening the iodine and substituting the lactate of calcium and a liberal supply of milk.

EXCURSIONS IN THERAPEUSIS.

To the Editor of THE LANCET.

SIR,—As one who has given an extensive clinical trial of the new methods and materials which Sir Thomas Horder refers to as X.Y.Z. 42, I welcome his address as an indication that the winds of these new doctrines are beginning to blow in high places, even if they evoke but Olympian laughter. The application of these doctrines in this hospital on 1200 control cases and 2000 test cases of diphtheria (as recounted in the *Medical Officer* of Jan. 24th, 1931[1]) has reduced the death-rate from 5·4 per cent. in the former to 2·6 per cent. in the latter. Based on nearly 600 test cases of scarlet fever the renal complications have been reduced from 11 per cent. to under 2 per cent. I have repeatedly seen the temperature fall to normal in 12 hours with a disappearance of the lesion in erysipelas after the exhibition of a suitable drug of this family. I have seen the thrombophlebitis following enteric fever instantly arrested with disappearance of all signs and symptoms in three days instead of the usual three weeks. I have seen cases of chronic boils which have resisted all other therapeutic measures clear up in a few days without recurrence when treated on these principles. These, and many other cases, lead one to think that there must be something in these ideas.

The knowledge of the hypothesis on which these methods are based and the study of the dark-ground picture of the blood are essential, as these drugs are potent for harm as well as good if rashly used. Sir Thomas's remark that "either there are particles in the plasma or there are not" must be regarded as rhetorical, as he must know that "our bodies are composed almost entirely of matter in its colloid (i.e., particulate) state" (E. S. Hedges, D.Sc., "Colloids," 1931). The colloid chemist will tell him that these particles are capable of condensation (flocculation and precipitin reactions) or dispersion (peptisation and lytic phenomena) with alterations in the continuous phase. If he examines sera from various diseases, he will see there are considerable differences in the appearance in their particles compared with the normal serum—in their number, Brownian movements, refractive index, and tendency to flocculate or not. On reading colloid chemistry one is impressed by the number of factors influencing a colloid system and amazed that already such a measure of success is possible therapeutically on these lines, seeing the methods of investigation at our disposal are so extremely crude and liable to very many fallacies. As to whether the hypothesis on which this work is based is correct or not (especially as to whether the effect of drugs is electronic or ionic) is a matter to be determined by the physical chemist, but it would seem that a case has been made out for investigation by experts in that line.

The following quotation is from Dr. Hedges's book :

> "A bird's nest may be made of twigs, straw, wool, and horsehair. The pure chemist is represented by an investigator who makes a thorough study of twigs, &c. . . . but who may not be interested in the most important object of his study—that is a bird's nest. A heap of twigs, &c. . . . does not make a nest, because a definite structure is involved and it is this combination of study of structure as well as chemical composition that forms one of the chief differences between the outlook of pure chemistry and colloidal chemistry. Colloid chemistry is a closer approach to the study of things as they exist."

Has not the tendency of biochemistry been largely to the study of twigs such as blood calcium, sugar or urea, rather than the investigation of the whole nest, the colloid system? Colloid chemistry must have an important bearing on medicine. Mr. McDonagh has made a valiant and, to a considerable degree, successful attempt to bring the researches of colloid chemistry into touch with clinical medicine. Whether his unitarian hypothesis has been stretched too far the future will show. The more recent studies in immunology seem to indicate that physico-chemical phenomena play a large but not the whole part in these events. I venture to prophesy that this will also be the final conclusion in the effects of therapeutic agencies.

---

[1] See also THE LANCET, 1930, ii., 579.

I hope that Sir Thomas Horder's address will lead to stimulation of this type of investigation, as very little seems to be known as yet of the behaviour of hydrophilic colloids under the influence of complex compounds.

I am, Sir, yours faithfully,
B. A. PETERS, M.D. Camb.,
Medical Superintendent, Ham Green Hospital
Jan. 26th, 1932. and Sanatorium, near Bristol.

BRONCHOSCOPY IN PULMONARY DISEASE.

To the Editor of THE LANCET.

SIR,—The frequent and important publications of Chevalier Jackson, his personal visits to this country, and the instruction courses which he organises, have been gradually establishing the value of bronchoscopy as a diagnostic and therapeutic measure. Your editorial comment last week on the excellent paper by Dr. Scott Pinchin and Dr. Morlock is well timed and will undoubtedly focus attention on the fact, not generally recognised, that access to the tracheo-bronchial tree by direct methods is possible and useful in a great variety of cases.

Their article is well illustrated by examples. The following two cases which came under my care at the Royal Chest Hospital are of interest.

(1) A.B., aged 24, male. Three years recurrent cough; hæmoptysis; irritation localised to a point under the inner end of the left clavicle. Coarse rhonchi heard over the upper part of the left chest, intensified on coughing. X ray negative. Sputum T.B. negative. Bronchoscopy. Papillomata of trachea and left bronchus discovered and removed. Recovery complete.

(2) C.D., aged 59, male. Six months increasing shortness of breath, eventually causing "gasping" on exertion and "tightness of chest" especially on bending. Winter cough; scanty sputum; occasional blood clots in sputum; loss of weight; no pain. On admission, slight cyanosis; very marked stridor; slight impairment of note and weak breath sounds left upper chest. Bronchoscopy. Large fibroma growing from the anterior wall of trachea just above the bifurcation. Removal through the glottis with complete relief.

A recent comprehensive collection by Ellen J. Patterson[1] of recorded cases of benign growths of the tracheo-bronchial tree revealed only 26 cases, a large percentage of which were diagnosed post mortem. These two cases, operated on within a relatively short time, suggest that what has been thought to be an extremely rare condition may prove to have a much higher incidence when bronchoscopy becomes more generally used as a means of diagnosis, and they raise an interesting consideration as to the extent to which such masses can be effectively removed through a bronchoscope.

While it is certain that bronchoscopy can and will become an important factor in pulmonary diagnosis and therapy, it is equally certain that there are great difficulties in the way of its becoming a method readily available for use outside the regular bronchoscopic clinics. A rigid technique, a complete set of good instruments, trained assistance, practice, and personal aptitude are essential for success. Since familiarity with all conditions of the larynx in health and disease is important, I venture to suggest that bronchoscopy remains a subject which, with few exceptions, is in the province of the laryngologist working in conjunction with physicians interested in diseases of the chest.

I am, Sir, yours faithfully,
London, W.. Feb. 1st, 1932. A. M. ZAMORA.

VACCINE TREATMENT IN INFECTIVE ARTHRITIS.

To the Editor of THE LANCET.

SIR,—Dr. Knyvett Gordon appears to have overlooked the main issue of my paper on the vaccine treatment of infective arthritis—viz., that vaccines given *under the conditions stated* do not yield results measurably superior to other forms of treatment when the series is large enough to permit of analysis, or the results by statistical methods. If Dr. Gordon believes that some other form of vaccine treatment is capable of yielding better results, I feel sure that all who are interested in this insidious and intractable disease would welcome its publication, but unless it is accompanied by data capable of statistical analysis it must be regarded as a personal opinion and not as scientific evidence. I might add that the results of stock and autogenous vaccines in several hundred cases were separately considered, and that the differences were not greater than could be ascribed to chance errors of sampling.

I am, Sir, yours faithfully,
PHYLLIS M. CONGDON.
Devonshire Hospital, Buxton, Feb. 2nd, 1932.

MEDICINE AND THE PRESS.

To the Editor of THE LANCET.

SIR,—The report of the discussion of this subject at the meeting of the Chelsea Clinical Society makes melancholy reading. All the speakers except one seemed to agree that newspaper readers are entirely incapable of exercising any power of independent judgment whatever, but appraise the "worth" of everything they read by the signature appended thereto. One cannot help thinking that this is sad. Sixty years of free education aided by the all-powerful press itself to have produced only this sheep-like mind! But perhaps our "able editors" are deceiving themselves. Let us hope so; for such a type of mind seems, if one may believe a "well-known authority," to be more characteristic of the press itself than the public.

> "But is it a good play, Mr. Bannal? That's a simple question.
>
> "Simple enough when you know. If it's by a good author it's a good play naturally."

I am, Sir, yours faithfully,
CHAS. E. THORNTON.
Beckenham, Kent, Feb. 1st, 1932.

*** *Dr. Thornton's view is the one consistently* held here. If medical information in the public press were put on the basis where political or financial information stands, signatures would only be needed in exceptional circumstances—the prestige of the paper would sign the articles.—ED. L.

REMEMBRANCE DAY IN LONDON.—The money collected in the London district on "Poppy Day" was £96,775. The poppies cost £11,900, and the administrative expenditure was £2492. Other figures are not yet available.

OBITUARY

JOHN PARLANE KINLOCH M.D. Glasg., M.R.C.P. Edin., D.P.H. Camb.,

CHIEF MEDICAL OFFICER, DEPARTMENT OF HEALTH FOR SCOTLAND.

THE death of Dr. Parlane Kinloch, on Jan. 31st, at the age of 46 years, brings to an abrupt end one of the most brilliant careers in public health administration in our times. His death was quite unexpected. He completed his week's work as usual last Saturday, and succumbed to a heart attack on the Sunday morning.

DR. PARLANE KINLOCH.

[Photograph by Morgan.

John Parlane Kinloch was a native of the Vale of Leven, Dunbartonshire, and was educated at Glasgow High School and Glasgow University, where he graduated M.B., Ch.B. in 1909. In 1910 he took the D.P.H. of Cambridge with distinction, and in 1913 the M.D. of Glasgow with commendation. A series of minor appointments followed. These included house surgeon and house physician in the Victoria Infirmary, Glasgow; resident medical officer in the Queen Charlotte Lying-in Hospital, London; pupil assistant in the Glasgow Public Health Department; and later resident medical officer at Ruchill Fever Hospital, Glasgow. From this last post he was appointed in 1914 deputy medical officer of health for the City of Aberdeen, and lecturer in public health in the University. It was in Aberdeen that he emerged as a force in public health administration. The war, however, interrupted his work. In 1914 he joined the R.A.M.C. (Territorial), and for three years commanded the Aberdeen University Officers' Training Corps. In 1918 he was in charge of a mobile hygienic field laboratory in France. After the war he resumed his appointments in Aberdeen, becoming reader in public health in 1923, and later in the same year succeeded Prof. Matthew Hay as medical officer of health and head of the University public health department. Dr. Kinloch carried to completion the work that Dr. Hay had begun, and he broke into new territory in a way that established Aberdeen as a pioneer city in public health administration. He was an inspiring leader of a team, and the team-work of Aberdeen in research and administration since Dr. Kinloch gave it impetus set the pace in Scotland. The Aberdeen team's studies in ultra-violet irradiation, dysentery, diarrhœal diseases in children, food poisoning, scarlet fever, measles. diphtheria, and maternal mortality have all affected public health practice. Dr. Kinloch was the first medical officer in Scotland to carry out on a comprehensive scale the hospitalisation of pneumonia—a lead which has been widely followed since.

But perhaps his greatest achievement in Aberdeen was to carry through, in the face of much determined opposition, the reorganisation of hospital services in Aberdeen. This reorganisation anticipated by several years the hospital clauses of the Local Government (Scotland) Act, 1929. Before that Act was passed, the poor-law hospital at Woodend had been transferred to the town council, run as an integral part of the city hospital services, and linked coöperatively with the Royal Infirmary and, for teaching and research purposes, with the University. Aberdeen in fact had already achieved what the Local Government Act contemplates for the rest of Scotland. This scheme of Dr. Kinloch's was part of his wider vision of a regional organisation—achieved already in part—and of a service that put all the facilities for modern methods of diagnosis and treatment behind and at the disposal of the general practitioner. He never forgot, nor did he allow his colleagues to forget, that the essential foundation of a good medical service was the general practitioner. Hence his hopes of a revised medical curriculum, the range of service he provided through the Aberdeen laboratories, and many other seemingly unrelated activities.

By 1928, when Sir Leslie Mackenzie retired from medical membership of the Scottish Board of Health, Dr. Kinloch's selection for the post of chief medical officer to the Department which took the Board's place was almost inevitable. He accepted the invitation of Sir John Gilmour, then Secretary of State for Scotland, to fill that office; but he did so with some trepidation, for he loved the close contact with realities which such work as superintendent of Aberdeen hospitals had given him. As chief medical officer for Scotland he was a success from the start. He reorganised and strengthened the medical department and, it may be said without disparagement of others, he humanised it, bringing it to a closer appreciation of the difficulties of medical men and other health workers in the field. He worked always to a vision of a regenerated Scotland, and preached the Greek ideal of physical and mental fitness. He was tormented by the contrast between his dreams and the law's delays, and the thousand and one petty impediments in the way of realising them. This torment flared out now and again; but it did not slacken his grip on the wheel or divert him from the course he had set. By one means and another he communicated his vision to others, not least his colleagues and assistants; he lifted the day's effort out of the humdrum, and related it to an inspiring purpose.

Such a personality, with a creative imagination always in play, could not but influence the direction of policy even in the short space of three years. He opened up new fields for the work of the Medical Research Council in Scotland, and secured the establishment of a scientific advisory committee to initiate and advise on medical investigations in Scotland, and to relate the fundamental work in biology and other sciences to the administration of the health services. Under his inspiration there is in process all over Scotland a knitting together of all the health agencies towards the central purpose of attaining positive fitness in the people. Abroad he was beginning to emerge as an international figure in public health. He has left behind him in the department in Edinburgh many projects and schemes and a whole stock of ideas in the rough. His death is a tragic loss. One administrative colleague summed up the general feeling in the department over his death by the remark: "Kinloch is the one man among us who is irreplaceable."

His work and the loyalty and affection of his colleagues speak for Dr. Kinloch, the man. His faults of temperament and the defects of his qualities did not matter to those who knew his bigness and felt the warmth and generosity of his friendship. He inspired affection and returned it in good measure. He was something of an evangelist. "It's a religion Kinloch has given us and a religion worth fighting for!" was how a Scottish veterinary inspector reflected over Dr. Kinloch's presidential address, entitled "The Science of Life," at the Scottish Sanitary Congress last year. This will serve as a pointer to the effect he produced in his public appearances. He was a born leader, and his death is a heavy blow to the medical profession and the public service of Scotland.

WALTER SMYTH, M.B. R.U.I.

THE death took place on Jan. 24th, in a nursing home in Belfast, of Dr. Walter Smyth, superintendent of the County Antrim Mental Hospital, in his fifty-seventh year. Dr. Smyth took his medical course in the Queen's College, Belfast, and qualified with honours at the early age of 21. Having acted as demonstrator of anatomy and physiology at the Queen's College, he specialised in ophthalmology, and was appointed assistant ophthalmic surgeon at the Royal Victoria Hospital. After a few years he turned his attention to psychological medicine, and was appointed assistant medical superintendent of the Antrim Mental Hospital in 1899, and in 1930 became superintendent. Our Belfast correspondent writes:—"Those who compare the up-to-date mental hospital at Antrim with the conditions which prevailed when he first went there can have some idea of what he accomplished. From the first his senior recognised his great capacity and allowed him ample scope for his gifts of organisation. He loved an outdoor life, and in the development of the farm attached to the hospital he found an additional outlet for his energies. Modest and unassuming he never sought the limelight but was revered by all his medical colleagues and beloved by his whole staff."

THE LATE MAJ.-GEN. H. HENDLEY, I.M.S.

Sir Leonard Rogers writes: I am glad of the opportunity to add a word of personal appreciation of Major-General Harold Hendley, I.M.S., to your full account of his long and varied service in India, during which he showed his competence in both military and civil positions, and eventually rose to high administrative posts. He was a typical example of the best type of I.M.S. officer in the palmy days of the service who was well-qualified to carry out most efficiently any of the multitudinous duties to fall to the lot of this service. His genial and kindly nature endeared him to all with whom he worked and played a large part in his success as an administrative officer. He saw much active military service in his earlier years and was thus well qualified to revert to administrative work on the military side after filling many important posts in the civil department of the Punjab. After his retirement he continued to take a deep interest in medical matters and regularly attended the Dufferin Committee meetings at the India Office where I had the pleasure of working with him, and he was also associated with the work of the Order of St. John of Jerusalem. He will be much missed by his very numerous friends, while I do not think he could ever have had an enemy.

PARLIAMENT

NOTES ON CURRENT TOPICS.

REASSEMBLY OF PARLIAMENT.

BOTH Houses of Parliament reassembled on Tuesday, Feb. 2nd, after the Christmas recess.

THE TRADE BALANCE.

In the House of Commons Major ELLIOT, the Financial Secretary to the Treasury, informed Mr. DENMAN that the approximate amount of revenue received from the duties imposed under the Abnormal Importations (Customs Duties) Act, 1931, to Dec. 31st, 1931, was £290,000.

In reply to Mr. LANSBURY, Leader of the Opposition, Mr. MACDONALD, Prime Minister, said that the Government had been engaged during the recess in studying the trade balance of the country in all its aspects. It had been decided to introduce a Bill to deal with the matter, and the necessary financial resolutions would be proposed by the Chancellor of the Exchequer on Thursday, Feb. 4th. It was the intention of the Government to press forward with the Bill and place it on the Statute Book at the earliest possible date. In view of the state of business before Easter, and particularly the urgency of passing the Trade Bill into law, the Government must regretfully ask private Members to sacrifice their parliamentary time.

TOWN PLANNING BILL.

Sir E. HILTON YOUNG, Minister of Health, in moving the second reading of the Town and Country Planning Bill, said that all the great representative bodies of local government had approved resolutions calling for legislation of this kind. No less than 18 private Acts had been passed conferring on particular local authorities powers similar to those which were being made general in this Bill. It was thought to be much better that those powers should be placed under the control of a public statute than that they should be conferred piecemeal by special private Acts. This Bill gave local authorities power to exercise reasonable foresight and control in planning the development of their localities. It was not a measure to confer arbitrary powers on a distant centralised office, but to put into the hands of the localities themselves powers of controlling their own destinies in these important matters. It was permissive in character. Population had doubled during the lifetime of the present generation, and the overcrowding of the towns made planning and reorganisation necessary to obtain more room for the people. The Bill would not impose restrictions on private enterprise, but it was intended to obtain the greatest measure of liberty and facility for private enterprise in development by means of adjustment in relation to the surroundings of the neighbourhood. Further, the Bill would enhance amenities of life in the country by regulating, for instance, the number of houses to be put up and the space that should be reserved between them. The Bill would enable local authorities to extend town planning schemes to undeveloped land and to land already built over. Power was also given to plan ahead for public improvements. Bigger areas than hitherto would come under the scope of regional planning, and local authorities would be enabled to deal with ribbon development by means of zones and restrictions, &c.

Sir S. CRIPPS intimated that the Opposition would support the Bill.

Sir WALKER SMITH moved the rejection of the Bill on the ground that, apart from the fact that there was far more important business to occupy Parliament at the present time, the measure was unnecessary, and indeed contrary to the public interest.

Lieut.-Colonel FREMANTLE said that the Bill was the only way to preserve the countryside. It was essential to have some kind of control to deal with future development. It was economical to look ahead. They must have this combination of social effort together with individual effort as civilisation advanced. He urged Members of the House to recognise that this Bill was the culmination of a general agreement among those who had studied the question. He had been asked by the London County Council to say that they gave their general support to the second reading of the Bill, although they reserved the right to suggest certain amendments.

After further debate the motion for rejection was negatived. and the Bill was read a second time without a division.

MEDICAL NEWS

University of Cambridge.

On Jan. 29th the following degrees were conferred :—

M.D.—F. W. Law.

M.B. & B.Chir.—M. E. D. Roberts, J. V. Lucas, G. T. Cook, Joseph Sowerbutts, and E. H. Hudson.

M.B.—E. H. W. Lyle, and L. E. Houghton.

B.Chir.—John Hughes, J. B. Tracey, M. A. Rushton, and W. A. C. K. Nanka-Bruce.

Royal College of Physicians of London.

At a meeting of the College on Jan. 28th, with Lord Dawson, the President, in the chair, the following candidates, having satisfied the Censor's Board, were admitted to the Membership :—

Charles Thomas Andrews, M.D. Belf., Philip Shaw Bell, M.B. Lond., Cyril Frank Cosin [illegible] Cowasjee, M.B. Lond., Jo[illegible] Mackenzie Deane, M.B. Melb [illegible] Cape Town, Richard White [illegible] John Enniss, M.B. Melb., [illegible] Panagodage Bertram Fern[illegible] Franklin, L.R.C.P., William James Gardiner, M.B. Toronto, Mohamed Abdel Hamid Gohar, M.B. Cairo, John Gordon, M.D. Leeds, Hagar Hethrington, M.B. Toronto, Edward Weston Hurst, M.D. Birm., David William Stuart Kaye, M.B. Lond., Joseph Victor Landor, M.D. Lond., Marjorie Low, M.D. Lond., Dame Anne Louise McIlroy, M.D. Glasg., Joseph Simdline, M.B. Lond., Adolf Markus Nussbrecher, M.B. Lond., [illegible] Camb., Harry Maynard Rennie, [illegible] Roberts, M.D. Manch., John [illegible], Mazhar Hussain Shah, M.B. [illegible], Neville Alexander Dyce Sharp, L.R.C.P., Mary Broadfoot Walker, M.B. Edin., Edward Johnson Wayne, M.B. Leeds, and Alexander Duncan Shanks Whyte, M.B., New Zealand.

Licences to practise were conferred upon 95 candidates (78 men and 17 women) who have completed the Final Examination of the Conjoint Board and have complied with the by-laws. The following are the names and medical schools of the successful candidates, viz. :—

G. Ashton, Oxford and Univ. Coll. ; H. C. Bamford, St. Bart.'s ; G. N. Barker, St. Thomas's ; H. F. Bateman, Camb. and St. Bart.'s ; H. J. Beard, Manchester ; H. Blumovitch, St. Bart.'s ; L. Bowen, St. Bart.'s ; F. E. Buckland, Oxford and St. George's ; C. Budeiri, M.D. Geneva, London ; A. H. Bulleid, Camb. and Bristol ; Winifred M. Burbury, Camb. and Leeds ; G. W. Causey, Liverpool ; M. Chalkowski, St. George's ; T. A. L. Davies, St. Thomas's ; Jane Druker, M.B. Manch. ; G. C. T. Du Toit, Witwatersrand and St. Bart.'s ; C. D. Evans, Camb. and St. Mary's ; Jennie G. Evans, Westminster ; H. T. Giblin, L.M.S.S.A., St. Mary's ; B. Gilbert, St. Thomas's ; A. M. Gill, Middlesex ; Rachel N. Gillespie, L.M.S.S.A., Royal Free ; A. C. Gladstone, St. Thomas's ; F. J. S. Gowar, Middlesex ; L. E. Green, St. Bart.'s ; Elizabeth M. Handfield-Jones, Oxford ; Joan G. Harcourt, Royal Free ; D. S. Hayes, St. Bart.'s ; S. T. Hayward, St. Bart.'s ; C. L. Heanley, Camb. and London ; W. P. Hedgcock, St. Thomas's ; A. Hollingsworth, St. Thomas's ; M. S. Holzman, London ; E. E. R. Hopkin-James, Camb. and Cardiff ; A. C. Howard, Univ. Coll. ; J. Howell, Camb. and Guy's ; S. V. Humphries, Camb. and St. Thomas's ; K. C. Jeffery, London ; P. W. E. Jones, Camb. and St. Bart.'s ; R. A. Jones, Camb. and London ; Alison F. Z. Judd, Royal Free ; J. J. Kempton, Bristol ; A. Kennedy, St. Thomas's ; E. A. Knappett, Univ. Coll. ; N. Langdon-Down, Camb. and London ; L. W. Lauste, St. Thomas's ; R. A. Q. Lay, Guy's ; O. C. Levine, Johns Hopkins and Univ. Coll. ; D. T. Lewis, St. Mary's ; J. T. R. Lewis, Middlesex ; W. H. Lewis, Camb. and Guy's ; Ethelberta M. Lynton-Low, Royal Free ; Jane S. McDowell, Charing Cross ; J. G. McGrath, Manchester ; N. F. Maclagan, Middlesex ; P. G. C. Martin, Camb. and Manchester ; R. G. Mayall, Camb. and St. George's ; W. A. Mayne, Camb. and St. Thomas's ; E. L. Monkhouse, Guy's : Irene P. Murray, King's Coll. ; P. Nair, Bombay and Royal Free ; P. G. A. Nambiar, Madras and Royal Free ; R. S. Ogborn, Univ. Coll. ; A. H. Osmond, Birmingham ; C. G. Owen, Edinburgh and St. Mary's ; R. H. Patel, Bombay and Birmingham ; J. C. Pedley, Middlesex ; E. D. Portman, Manchester ; S. Prakash, M.B. Rangoon, Charing Cross ; G. Ramage, M.B. Manch. ; J. Reeve, Westminster ; E. R. B. Reynolds, St. Thomas's ; Irene P. Rowlands, Charing Cross ; P. G. Roberts, St. Bart.'s ; H. Rosenberg, Guy's ; H. W. Salmon, Middlesex ; J. L. S. Scott, Camb. and St. Bart.'s ; C. K. Shain, Leeds ; R. F. Simkin, St. Mary's ; R. E. H. Simpson, St. Thomas's ; E. R. Sinton, Birmingham ; W. L. Sleight, Bristol ; W. G. Smith, L.D.S., Cardiff ; W. P. Stamm, Guy's ; Joan W. Stelfox, Liverpool ; M. G. Stratford, Univ. Coll. ; G. H. Taylor, Guy's ; H. C. M. Walton, Camb. and St. Mary's ; Clara M. Warren, Royal Free ; Grace E. Watson, Royal Free ; H. A. T. Wells, L.M.S.S.A., Madras and Guy's ; Shirley E. Whitaker, Univ. Coll. ; H. T. S. Wise, King's Coll. ; F. H. Wood, Birmingham ; W. Woolley, Bristol.

The undermentioned diplomas were conferred (jointly with the Royal College of Surgeons) upon the following candidates :—

Diploma in Public Health.—G. F. Bramley, J. E. Cheesman, M.M.D. Chughtai, S. N. Consul, Doris V. Douglas-Norman, Ruth C. Finn, R. C. Jones, P. M. Kaul, Dorothy M. Llewellin, Janet M. Macmillan, L. D. Richards, F. A. H. Simmonds, J. E. Stokes.

Diploma in Laryngology and Otology.—V. Y. Apte, M. Basheer, V. U. Chitale, N. M. Cuthbert, H. J. Eizenberg, E. W. Ingle, H. Y. Khwaja, D. A. P. Macalister, N. D. Matson, C. K. C. Misra, B. F. Niblock, E. R. G. Passe, M. A. H. Siddiqi.

Diploma in Psychological Medicine.—C. E. Allen, J. C. Batt, F. H. Beare, H. C. Beccle, C. L. C. Burns, E. N. Butler, Irene Dixon, W. J. McCulley, F. L. McLaughlin, J. H. Mulvany, E. U. H. Pentreath, Irene Yates, G. C. Young.

Sir John Rose Bradford was elected a Member of the Executive Committee of the Imperial Cancer Research Fund. Dr. Arthur Shadwell was re-elected the College representative on the Council of the Queen's Institute for District Nursing, and Dr. H. Charles Cameron was appointed a representative on the Child Guidance Council.

The Milroy lectures, on the Rôle of the Hæmolytic Streptococci in Infective Disease, will be delivered by Prof. Cyril Okell on Feb. 18th, 23rd, and 25th, the Goulstonian lectures on the Pathology and Treatment of Anæmia, by Dr. J. L. Witts, on March 1st, 3rd, and 8th, and the Lumleian lectures on the Borderlands of Medicine, by Dr. C. E. Lakin on March 10th, 15th, and 17th, all at 5 P.M. at the College, Pall Mall East.

Society of Apothecaries of London.

At recent examinations the following candidates were successful :—

Surgery.—R. R. Clipstein, St. Mary's Hosp., and R. F. Hawke, London Hosp.

Medicine.—G. S. N. Hughes, St. Mary's Hosp. ; I. S. Lloyd, Royal Colleges, Edinburgh ; and H. C. Pain, Middlesex Hosp.

Forensic Medicine.—M. Belo-Zercovsky, London Hosp. ; W. E. P. Corbett, St. Mary's Hosp. ; R. F. Hawke, London Hosp. ; I. S. Lloyd, Royal Colleges, Edinburgh ; A. J. McBrearty, Queen's Univ., Belfast ; T. D. Norton, Univ. of Sheffield ; B. Rivlin, Univ. of Frankfort and Middlesex Hosp. ; and L. G. Yendoll, Guy's Hosp.

Midwifery.—F. Crowther, Guy's Hosp. ; M. Ditton, Univ. of Munich and Royal Free Hosp. ; and R. G. Joyce, St. Bart.'s Hosp.

The following candidates, having completed the final examination, have been granted the diploma of the Society entitling them to practise medicine, surgery, and midwifery :—M. Ditton, R. F. Hawke, and B. Rivlin.

National University of Ireland.

On Jan. 16th the following degrees and diplomas were conferred in University College, Cork :—

M.D.—W. H. Kelleher.

M.A.O.—D. St. A. Atkins.

M.B., B.Ch., and B.A.O.—P. J. Burke, C. J. Callanan, E. F. McCarthy, P. M. McSwiney, J. J. Murphy, Thomas Nunan, Patrick O'Donnell, John Walsh, and W. F. Whelton.

B.Sc. (Public Health).—Mary C. Cross and P. F. Fitzpatrick.

D.P.M.—C. B. Molony.

Central Association for Mental Welfare.

A course of lectures and clinical work on Mental Deficiency and other Mental Conditions closely allied to it has been arranged by the University of London Tutorial and Extension Classes Council in coöperation with the Central Association for Mental Welfare, and will be held, if enough applications are received, from April 11th to 23rd at the University of London, South Kensington. It is intended for qualified medical practitioners, and will be based on the requirements for the University of London Diploma in Psychological Medicine. Communications should be addressed to Miss Evelyn Fox, c/o University Extension Department, University of London, Imperial Institute-road, South Kensington, S.W. 7.

Medical Society of London.

In view of the present economic condition of the country, the annual dinner of this society will not be held this year.

French Ophthalmological Society.

This society is holding its fiftieth anniversary meeting from July 18th to 21st. It is to be the occasion of special celebrations. Requests for information should be sent to Dr. René Onfray, 6, avenue de la Motte Picquet, Paris VII.

University of Durham College of Medicine.

Twelve lectures and demonstrations on Diseases of Children are being given by Dr. J. C. Spence on Thursdays at 4 P.M., beginning on Feb. 4th, at the Babies' Hospital and Royal Victoria Infirmary, Newcastle. Particulars may be had from the Registrar of the College of Medicine.

Abernethian Society.

Prof. Hugh Cabot of the University of Michigan has promised to give the summer sessional address to the Abernethian Society, St. Bartholomew's Hospital, on Thursday, April 14th. His subject will be Further Travels with the North American Indians, and the address will be given at 8.30 P.M. in the medical and surgical theatre. It will be illustrated by a film.

Institute of Psycho-analysis.

A course of lectures is being given to medical practitioners and students, under the auspices of this Institute, at the London Clinic of Psycho-analysis, 36, Gloucester-place, W. 1, on Friday evenings at 8.30 P.M. during February. The lecturer, Dr. John Rickman, will deal with Psycho-analytical Contributions to Psychiatry, and it is proposed to give time to discussion and questions at the close of each lecture.

Medical History for Nurses.

A course of informal lectures on medico-historical topics to the nursing staff of the East London Children's Hospital was inaugurated on Jan. 29th by Mr. Wilfred Trotter, F.R.S., who took the chair for a lecture on "The Drama of Appendicitis: the Stage and the Actors," by Dr. W. R. Bett, late house surgeon and casualty officer. A vote of thanks to the chairman and to the lecturer was proposed by Sir Ernest Graham-Little, an "old Shadwellian," and heartily carried by a large and appreciative audience which included Sir Buckston Browne, Sir D'Arcy Power, Mr. Warren Dawson, several members of the visiting staff, and nurses from the hospitals in the neighbourhood.

Births, Marriages, and Deaths

BIRTHS.

BLAXILL.—On Jan. 30th, at Crinnis House, Southend-on-Sea, the wife of Bernard Blaxill, M.A., M.B., of a daughter.

FLEMING.—On Jan. 31st, at Finchley-road, N.W., the wife of Dr. Gordon Fleming, of a daughter.

RUSSELL.—On Jan. 24th, at a nursing home, Bradford, the wife of Henry Stewart Russell, M.B., Ch.B., of Oakroyd, Manningham-lane, Bradford, Yorks [illegible]

WILSON.—On Jan. 26th, 1932, at 45, [illegible]
on-the-Hill, to Ruth, wife of Henry [illegible]
—a son.

MARRIAGES.

PURVES—MACWHIRTER.—On Jan. 28th, at Abbots Langley Church, Kenneth MacLennan Purves, M.B., F.R.C.S. Ed., Chagford, Devon, to Catherine Marian Weir, youngest daughter of Mr. W. MacWhirter and the late Elizabeth MacWhirter.

ROBERTS—AYLING.—On Jan. 27th, at Great Doddington, Northants, Michael Edward Dale Roberts, M.B. Camb., to Mary Christabel, younger daughter of Sir William Ayling, I.C.S. (Retired).

DEATHS.

HOPE FOWLER.—At a nursing home, on the 27th ult., Julia, dearly beloved wife of Dr. Wm. Hope Fowler, 8, Midmar-drive and 21, Walker-street, Edinburgh, youngest daughter of the late James Cant, Esq., of Ore Bridge, Thornton, Fife.

GLASIER.—On Jan. 29th, at Cedar Tree House, Madingly-road,
[illegible] a long illness, Howard Glasier, M.A.,
[illegible] Mildenhall), aged 60.
[illegible] 31st, Dr. J. P. Kinloch, Chief Medical
[illegible] for Scotland, aged 46.

MALLAM.—On Jan. 24th, at Norwich, Harry Guy Mallam, M.R.C.S., L.R.C.P. (Retired), aged 58.

REID.—On Jan. 28th, at "Burdale," Seaview-road, The Salterns, South Hayling Island, Robert Galbraith Reid, M.B., C.M., late of Surbiton and London, in his 66th year.

RYLAND-WHITAKER.—On Jan. 28th, at Bruntsfield-crescent, Edinburgh, Joseph Ryland-Whitaker, B.A., M.D. Lond., F.R.C.P. Edin., Lecturer of Anatomy, Surgeons' Hall, Edinburgh, in his 85th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Feb. 8th.—5 P.M., UNITED SERVICES (at the Royal Army Medical College, Grosvenor-road, S.W.). Paper: Major W. R. Galwey: Some Medical Problems of Mustard-gas Poisoning. Tea will be served in the Mess at 4.30 P.M.

TUESDAY.—5 P.M., THERAPEUTICS AND PHARMACOLOGY. Discussion: Investigation and Treatment of Certain Cases of Disease of Muscle and Nerve. Openers: Dr. A. C. Hampson and Dr. E. C. Warner. Other speakers will take part. 8.30 P.M., PSYCHIATRY. Paper: Dr. Edward Glover: The Principles of Psychiatric Classification.

FRIDAY.—5.30 P.M., CLINICAL. Cases: 4.30 P.M. Dr.
J. F. Halls Dally: 1. [illegible]
Dr. Bernard Myers: [illegible]
East: 3. Coarctation [illegible]
Dr. F. Parkes Weber: 4. Pernicious Anæmia. 5. Orthostatic Œdema. Dr. Hugh Stannus: 6. Neoplasm of Lung. Mr. Harold Edwards: 7. Hæmolymph Angioma. 8. Hemiglossectomy for Carcinoma. 9. Rectal Prolapse. Dr. J. D. Rolleston: 10. Striæ Atrophicæ after Rheumatic Fever. Dr. H. Avery: 11. Unequal Pulses. 8.30 P.M., OPHTHALMOLOGY. (Cases at 8 P.M.) Papers: Mr. Malcolm Hepburn: Differential Diagnosis of Certain White Deposits in the Fundus. Mr. Ernest Clarke: Some Remarks on Tay's Guttate Choroiditis. Cases: Mr. O. Gayer Morgan: 1. Congenital Hypoplasia of the Facial and Oculomotor Nuclei in Association with other Congenital Abnormalities. Miss Rosa Ford: 2. Pigmented Cyst in the Iris. 3. Dislocated Lens which has been in the Anterior Chamber for Two Years. Other cases will be shown.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, Feb. 11th.—8.30 P.M., Discussion in Paddington Town Hall on the Value of Endoscopic Methods. Openers: Mr. V. E. Negus (Trachea and Bronchi) and Mr. H. S. Souttar, (Œsophagus).

MEDICAL SOCIETY OF LONDON.

MONDAY, Feb. 8th.—8.30 P.M., Discussion on Chronic Toxic Cholecystitis. (Openers: Mr. Harold Dodd and Dr. Arthur Davies.)

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, Feb. 12th.—7.15 P.M., Dinner Meeting at the Rembrandt Hotel. Discussion: Public Health Work in its Relationship to the General Practitioner. Openers: Dr. J. B. Howell and Dr. James Fenton.

PADDINGTON MEDICAL SOCIETY.

TUESDAY, Feb. 9th.—9 P.M. (at the Great Western Royal Hotel, Paddington). Dr. W. S. C. Copeman: The Spa Treatment of the Rheumatic Diseases. The address will be illustrated by a film.

BIOCHEMICAL SOCIETY.

FRIDAY, Feb. 12th.—5 P.M. (at the Lister Institute, Chelsea Bridge-road, S.W.). Communications.

WEST KENT MEDICO-CHIRURGICAL SOCIETY, Miller General Hospital, Greenwich, S.E.

FRIDAY, Feb. 12th.—8.45 P.M., Dr. W. Smith: How Pathology Can Help the Clinician.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY, Feb. 8th.—5 P.M., Dr. J. A. Ryle: Natural History of Duodenal Ulcer.

WEDNESDAY.—5 P.M., Prof. H. A. Harris: Comparative Anatomical Aspect of Disease with Special Reference to Bone Growth.

FRIDAY.—5 P.M., Prof. Harris (second lecture).

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Feb. 8th, to SATURDAY, Feb. 13th.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Wed., Dr. Maurice Davidson: The Treatment of General Management of the Phthisical Patient, 4 P.M. Open to Members only.—KING'S COLLEGE HOSPITAL, Denmark Hill, S.E. Thurs.,
3–4 P.M., C [illegible] Terence
East.—ST. [illegible] W.C.
Fri., 3 P.M., [illegible] ises by
Mr. Malcolm [illegible] IPTION,
Brompton. [illegible] of the
Chest. All [illegible] OMEN,
Arthur-street [illegible] ynæco-
logy. All [illegible] cester-
square. Post-graduate Course in Dermatology.
Daily at 2 and 6. Lectures, 5 P.M. Tues. and Thurs.—
ROYAL FREE HOSPITAL, Gray's Inn-road, W.C. Fri.,
5 P.M., Antenatal Demonstration by Dame Louise
McIlroy. Further particulars from the Fellowship.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, University-street, W.C.

TUESDAY, Feb. 9th.—5.15 P.M., Prof. A. E. Boycott: Hypertrophy and Atrophy.

CHARING CROSS HOSPITAL MEDICAL SCHOOL.
SUNDAY, Feb. 7th.—10.45 A.M., Dr. K. S. Smith: Angina Pectoris. 11.45 A.M., Mr. E. A. Crook: Diagnosis of Diseases of the Rectum.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark-hill, S.E.
THURSDAY, Feb. 11th.—9 P.M., Mr. J. B. Hunter: Chronic Appendicitis.

ST. BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE, West Smithfield.
MONDAY, Feb. 8th, and following THURS. and FRI.—5.30 P.M., Dr. L. Findlay: Feeding and Nutritional Disease of the Infant.

GUY'S HOSPITAL, London Bridge, S.E.
MONDAY, Feb. 8th.—5 P.M., Prof. H. A. Harris: The Use of X Rays in Physiological Investigations.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.
TUESDAY, Feb. 9th.—3.15 P.M., Dr. B. Williamson: Heart Failure.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.
WEDNESDAY, Feb. 10th.—4 P.M., Dr. S. Wallis: Artificial Pneumothorax.

NATIONAL HOSPITAL, Queen-square, W.C.
MONDAY, Feb. 8th.—2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Symonds: Disseminated Sclerosis and Allied Conditions.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Grainger Stewart: Vascular Lesions of the Spinal Cord.
WEDNESDAY.—2 P.M., Dr. Martin: Out-patient Clinic.
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Critchley: Cerebral Sclerosis of Childhood.
FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Walshe: Cerebral Tumours.

CITY OF LONDON MATERNITY HOSPITAL, City-road, E.C.
THURSDAY, Feb. 11th.—5.30 P.M., Dr. S. Owen: The Newly-born Baby.

ST. PETER'S HOSPITAL, Henrietta-street, W.C.
WEDNESDAY, Feb. 10th.—3 P.M., Mr. A. H. Harkness: Treatment of Acute Gonorrhœa.

ST. MARK'S HOSPITAL, City-road, E.C.
THURSDAY, Feb. 11th.—4.30 P.M., Mr. C. N. Morgan: Surgical Anatomy of the Rectum, &c.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Feb. 9th.—5 P.M., Dr. H. C. G. Semon: Diseases of the Buccal Mucous Membrane.
THURSDAY.—5 P.M., Dr. H. Haldin-Davis: Pruritus, Prurigo, Lichenification.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James' Hospital, Ouseley-road, Balham.
WEDNESDAY, Feb. 10th.—4 P.M., Dr. H. W. Barber: Common Skin Diseases.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.
FRIDAY, Feb. 12th.—4 P.M., Mr. N. Rankin: Differential Diagnosis in a Case Complaining of Nasal Discharge.

MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY, 11, Chandos-street, Cavendish-square, W.
THURSDAY, Feb. 11th.—8.30 P.M., Dr. James Young: Individual Psychology and its Philosophical Implications.

NATIONAL COUNCIL FOR MENTAL HYGIENE.
WEDNESDAY, Feb. 10th.—5.30 P.M. (at 11, Chandos-street, Cavendish-square, W.). Mr. George Ives: Penal Methods of the Past and Present.

ST. MARY'S HOSPITALS, Manchester.
FRIDAY, Feb. 12th.—4.15 P.M. (at the Whitworth-street West Hospital), Dr. Lacey and Dr. Addis: Antenatal Demonstrations.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Feb. 10th.—4 P.M., Dr. M. B. Ray: Prevention and Treatment of Industrial Rheumatism.

FACULTY HALL, St. Vincent-street, Glasgow.
TUESDAY, Feb. 9th.—4 P.M., Dr. D. Baird: Infective Conditions of Urinary Tract during Pregnancy, &c.

EAR, NOSE, AND THROAT HOSPITAL, Glasgow.
WEDNESDAY, Feb. 10th.—4.15 P.M., Demonstration by the Staff.

INDEX TO "THE LANCET," VOL. II., 1931.

THE Index and Title-page to Vol. II., 1931, which was completed with the issue of Dec. 26th, is now ready. A copy will be sent gratis to subscribers on receipt *of a* post-card addressed to the Manager of THE LANCET, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

Appointments

FRASER, K., M.B., Ch.B. Aberd., D.P.H., has been appointed Medical Officer of Health for Cumberland.

HAMILTON, D. R., M.B., Ch.B. D.P.H. Glasg., D. P.H., Medical Officer of Health for Shipley.

HENDRY, M.D., B.S. Lond., one of the Medical Referees under the Workmen's Compensation Act for the Districts of the Daventry and Rugby County Courts (Circuit No. 23).

SANKEY, J. N., M.B. Birm., F.R.C.S. Eng., Surgeon for out-patients, Queen's Hospital, Birmingham.

STRÖM-OLSEN, ROLF, M.B., B.Ch., D.P.M., Senior Assistant Medical Officer, Cardiff City Mental Hospital, Whitchurch, near Cardiff.

Vacancies

For further information refer to the advertisement columns.

Ards District Hospital, Northern Ireland.—M.O. £500.
Ashton-under-Lyne, District Infirmary.—H.S. At rate of £150.
Auckland General Hospital, New Zealand.—Med. Supt.
Birmingham, Selly Oak Hospital.—Biochemist. £400.
Birmingham and Midland Eye Hospital.—Res. Surg. O. £150.
Bradford Municipal General Hospital, St. Luke's.—H.P.'s and H.S.'s. Each at rate of £200.
Brighton, New Sussex Hospital, for Women and Children.—H.P. and H.S. Each £100.
Brighton, Sussex Eye Hospital.—Hon. Asst. Anæsthetist.
Brighton, Sussex Maternity and Women's Hospital.—Res. H.S. £130.
British Institute of Radiology, 32, Welbeck-street, W.—Sub-Editor.
Cambridge, Addenbrooke's Hospital.—H.P. At rate of £130.
Cardiff, Canton Medical Relief District.—Temp. M.O. £200.
Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Asst. Surg. Also Third Res. H.S. At rate of £75.
Charing Cross Hospital.—Res. M.O. £350.
Derby, Derbyshire Royal Infirmary.—Cas. O. £150.
Dorchester, Dorset County Hospital.—H.S. At rate of £160.
Dudley, Guest Hospital.—H.S. £200. Also Asst. H.S. £170.
East London Hospital for Children, Shadwell, E.—Dermatologist.

South-Western Fever Hospital, London-road, Stockwell, S.W.—Res. Med. Supt. £900.
Talgarth, Breconshire, South Wales Sanatorium.—Asst. Res. M.O. £250.
Tunbridge Wells and Counties General Hospital.—H.S. £160.
W [illegible] lic Surgeon.
W [illegible] .—Non.-Res. Cas. O. [illegible] Asst. Anæsthetist.
W [illegible] *d, N.W.*—Hon. 2nd Radiologist.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Chipping Norton.

NOTES, COMMENTS, AND ABSTRACTS

THE TREATMENT OF PERSISTENT OFFENDERS.*

BY HAROLD FREIZE STEPHENS, M.R.C.S.,
MEDICAL SUPERINTENDENT, COLESHILL HALL COLONY,
NEAR BIRMINGHAM.

THE "somewhat serious disturbance" that occurred recently at the Dartmoor Convict Prison should serve to emphasise the need of dealing more effectively with the persistent offender, especially in the days of his youth and before he has begun that career of anti-social activity which renders him a nuisance and a menace to the State.

For all practical purposes persistent offenders may be divided into two groups: the persistent petty offender and the habitual criminal. The first group contains that heterogeneous collection of weak-minded persons that has always been found in prison, and for whom a modified prison discipline has gradually evolved. Some of these persons become certifiable under the Lunacy Acts and are transferred to mental hospitals, but for the majority of them special observation and training has to be provided. Since 1914, however, a large proportion of these weak-minded offenders, who were continally in and out of prison, have been dealt with under the Mental Deficiency Acts. These Acts have proved a great boon to the Prison Medical Service. They set up new standards to which persistent offenders could be referred and by means of which they could be examined and judged. It is computed that since they came into operation in 1914 the daily average prison population has been reduced by at least 200. Much more remains to be done in this respect. The shortage of institutional accommodation for mental defectives throughout the country is still very serious. The absence of such provision is directly responsible for many of these unfortunate persons falling into crime and is a grave injustice to them. The present position is most unsatisfactory, and in the public interest it is very necessary that the local authorities should endeavour to cope with it as soon as possible.

The Weak-minded Offender.

Some of the earlier workers under the Mental Deficiency Acts were inclined to go to extremes, and a few years ago it was asserted that a very large proportion of all offenders were mental defectives. Careful examinations since then have shown that these statements were exaggerated. Without such examinations, however, this knowledge could not have been obtained. There is in our prisons to-day a considerable class of the persistent petty offender, the members of which manifest some mental abnormality that does not render them capable of being dealt with either under the Lunacy or the Mental Deficiency Acts. New definitions and standards would appear again to be required. These can be attained only by a series of investigations by trained observers, and it is desirable that this research work should be undertaken as soon as possible.

Our Prison Medical Service is probably the finest in the world. Its officers pay special attention to the study of psychology and of mental disease and they are a devoted band of workers. At best, however, their experience is limited, and they certainly would be the first to welcome consultative coöperation with recognised experts outside the Service. Such professional assistance should be available for their use not only for the research work here suggested but on all occasions on which it may be necessary. For some years now a panel of educational advisers has afforded useful assistance in connexion with the training in our local prisons. A panel of psychological advisers, composed largely of medical psychologists, should prove to be equally valuable.

The psychological understanding of the persistent offender should begin, however, before his entry into prison. Our stipendiary magistrates and our justices of the peace are second to none in their appreciation of this fact and of the value of dealing with the individual rather than with the offence. It is desirable, therefore, that they should have the assistance of specially qualified social workers, of psychiatrists and physicians, in order that they may be provided with reliable reports of the physical, psychological, and environmental aspects of the offenders with whom they have to deal. Towards the same end coöperation should be established between our courts and the early treatment centres now being instituted under the Mental Treatment Act.

Supervision and Training.

The second group of persistent offenders is composed of the habitual criminals. These are dealt with to-day in accordance with the requirements of the Prevention of Crime Act, 1908, as amended by the Criminal Justice Administration Act, 1914, and the Indictments Act, 1915. The Prevention of Crime Act, 1908, consists of two parts. Part I. is concerned with the reformation of young offenders and initiated "the Borstal System." Part II. introduces the principle of "preventive detention" in the treatment of the habitual criminal. The Borstal system deals with persons of 16 to 21, and may be extended to those of 23 years of age, where such persons are convicted on indictment of such offences as render them liable to be sentenced to penal servitude or imprisonment, and it appears to the Court that, by reason of their criminal habits or tendencies, or because of their association with persons of bad character, it is expedient that they should be subject to a period of training in a Borstal institution, such period being for not less than two nor more than three years. Preventive detention is applicable to those persons who since attaining the age of 16 years have at least three times previously to the conviction of the crime with which they are charged been convicted of a crime, and it is found that they are leading persistently a dishonest or criminal life. By the system of preventive detention habitual criminals sentenced to penal servitude can receive for the protection of society an additional sentence of prolonged seclusion under less rigorous conditions in a special establishment for a period of not less than five and not more than ten years.

The Prevention of Crime Act, 1908, therefore, is capable of dealing with offenders from the age of 16. English law, however, has provided for their treatment before that age. Thus, "delinquent" children under 12, or under 14 if not previously convicted, and "convicted" children over 12 and under 16 at the time of conviction may be sent for training in a Home Office school. The Probation Acts, moreover, may be invoked on behalf of children of all ages. Means accordingly are available for the satisfactory supervision of a possible persistent offender from an early age.

Unfortunately, in many cases these facilities have not been used, and in many others the valuable institutional training thus provided has been delayed unduly long. Many have been placed on probation who should have been committed to Home Office schools or Borstal institutions. Many have been sent to Borstal institutions who would have had a better chance of reformation had they been sent to Home Office schools at an earlier age; many, too, have been sent for Borstal training at the age of 19 or 20 years who might with advantage to themselves and others have been sent for such training when they were 16 to 17 years old. These lapses in the administration of the law, largely due to false sentiment, are to be regretted. It is to be hoped that means will be found to limit the frequency of such lapses in future. It cannot be emphasised too frequently nor too forcibly that when the offender is found to require training away from his home and surroundings the earlier he is sent to a Home Office school or a Borstal institution the more certain are the chances of his reform. Not to afford the young offender these facilities when he is in need of them is to treat him with unnecessary injustice.

---

* Based on a paper prepared for the National Council for Mental Hygiene, and submitted on their behalf to the Committee on Persistent Offenders appointed by the Home Office.

Moreover, in accordance with the law as it stands to-day, it is necessary that the period of detention, in school or institution should be specified by the court in each case. This has serious disadvantages. As the court is unable to forecast the future it is unable to tell exactly how long a period should prove necessary for the reformation of any particular offender. There are lads who, on leaving the Home Office school, would benefit by a period of detention in a Borstal institution. In the case of the majority of the entrants to these institutions a sentence of three years should suffice; in the case of others, three years would not be enough. There are men to-day who, in spite of Home Office school and Borstal commitments, are unable to live as law-abiding citizens. The aim of the system should be, as our enlightened courts are well aware, not so much the serving of a sentence as the training of an individual. If that training should require a longer time in the case of certain individuals, then that extra time should be available for them. Definite sentences of fixed duration preclude the possibility of such an arrangement; in certain cases the Home Secretary has powers to prolong the period of training, but usually the training ceases when the sentence comes to an end, unfit though the individual may be to resume a free life in the community. This is unfair both to the individual and to the community. In dealing with persistent offenders "the indeterminate sentence" should prove to be more effective.

The Indeterminate Sentence.

The idea of the indeterminate sentence has been discussed in Europe for many years. It is an old English idea, and appeared first in the cruder forms of the transportation and ticket-of-leave systems that prevailed here in the eighteenth century. It owes its modern revival to America where the indeterminate sentence has a different meaning to that by which it usually is understood in Europe, and possibly also in England to-day. In Europe the indeterminate sentence appears to mean what we in England now know as preventive detention; it seems to signify a state of more or less perpetual segregation for the socially unadaptable, whether these are those who, by repeated acts, cause trouble and nuisance to the community, such as vagrants and drunkards, or those who, by persistence in serious crime, tend to become a terror and a menace to the State. Such a conception of the indeterminate sentence emphasises its value chiefly as a custodial measure, and, in the opinion of many, would make of it a terrible instrument of social retaliation which would tend to increase rather than to diminish the incidence of serious crime. In America, however, the indeterminate sentence is regarded as a useful instrument of reform, and about 40 States of the Union have accepted it as such. In these States it is considered to be not so much a measure of security, of communal protection against the hardened habitual criminal or social nuisance, as a means of affording the offender such supervision, control, and training as will enable him to learn to avoid, actively to resist, and even to detest a life of continual crime. It is this conception of the indeterminate sentence that is adopted in this paper. So considered, this useful invention becomes a measure of greater hope and value in the treatment of the persistent offender, especially if he is not of mature age.

According to this ideal the principle of the indeterminate sentence may be said to contain three essential elements. These are: (1) a sentence of indefinite duration as to time so as to enable the offender to be kept under supervision and control until he is reformed; (2) the application during this period of appropriate methods of mental, moral, and physical training calculated to effect that reformation; (3) the subsequent granting of parole and licence so arranged as to test the results of the training and the durability and value of the reformation prior to the offender's final discharge.

The Road to Reform.

The fixed sentence, as has been pointed out by several observers, carries with it little or no influence on character or disposition. The prisoner knows the extreme limit of his confinement. If it is short, he bears with it, and concentrates his thoughts on plans for pursuing his predatory instincts with greater caution in the future. If the period of the sentence is long, the criminal may strive by a show of good conduct to obtain an earlier release; but his way to it is through quiet and docile behaviour and an appearance of virtue, and not through a better training for the struggle of life or a greater disposition to face it with courage and honesty. His plan is to impress his jailers and not to improve himself. On the other hand, as the late Viscount Cave maintained, when an offender is sentenced to a restraint to which no fixed limit is assigned, but with an intimation that his fate lies in his own hands, that if he will but use the opportunities of self-improvement which are offered to him and fit himself bodily and mentally for an ordinary decent life, release will be his—his thought and his desires receive a new impetus; he turns to the tasks which are set to him and strives through their accomplishment to gain freedom and a new existence. In doing so he attains to a clearer vision and a better knowledge of himself and eventually achieves a habitus of life that is not consistent with criminal tendencies.

Preventive detention as at present applied in England is of little reformative value, as in practice it tends to become available only for the middle-aged whose habits are already formed. A complete change in the attitude of mind of such persons is of rare occurrence. The principle of the indeterminate sentence as outlined in this paper and rendered applicable to all offenders up to the age of 30 years would be a surer means of preventing the development of the habitual criminal. Its adoption would require the institution of a post-Borstal establishment in the form of a training colony for persons of 21 to 30 years of age. For persistent offenders over the age of 30 on whom systematic training for a period of years has had no beneficent effect there would still be available, as at present, the preventive detention prisons, places of custodial care, as distinct from the Home Office institutions for intensive and systematic training.

There would be then three stages on the road to reform—the Home Office school, the Borstal institution, and the adult training colony. The links between these stages would be the probation system and the Borstal Association. If necessary, progress between the three stages would be continuous so that the training of any particular individual need not be interfered with from school to colony. In this scheme probation would play an important part. It would be used to the fullest possible extent, but only in suitable cases. It would never take the place of necessary institutional training. The complete system of school, institution, and colony should be under the control of a small body of experienced persons appointed by the Prison Commission for the whole country and giving their whole time to the work. Only from such a board of control could uniform and skilled methods of administration and treatment be expected. Further, an advisory committee of medico-psychological and educational experts should be available for consultation by this board of control. Finally, the whole scheme of training thus outlined would fail to function satisfactorily without a comprehensive system of effective after-care. The work of the Home Office schools and Borstal Association in this respect should be maintained. Their efforts should be coördinated, and, where necessary, augmented by the establishment of local committees. These committees would best be organised by the local education authorities, the local probation committees and voluntary societies interested in this work being represented on them.

Summary.

One of the results of the working of the Mental Deficiency Acts was to reduce the number of persistent offenders in prison, where there is still a vast amount of clinical material for psychological examination.

Research should elicit data on which new statutes could be based, the effect of which would be still further to reduce the number of persistent offenders. To help with this research work a panel of psychological advisers should be available for local prisons.

For such offenders as remained to be dealt with by the prison authority systematic training should be available in Home Office school, Borstal institution, and a new type of establishment to be known as the *adult training colony* for offenders from 21 to 30 years of age. For persistent offenders over the age of 30 the preventive detention prisons should be retained.

The complete training system of school, institution and colony should be under the direction of a central board of control who should have the assistance of an advisory committee of medico-psychological and educational experts.

The principle of the indeterminate sentence should be applied to all offenders receiving such training, which, if necessary, should be continuous from school to colony.

In connexion with the use of the indeterminate sentence there should be neither a maximum nor a *minimum period fixed by statute.*

The final discharge of offenders under such sentences should be in the power of the central board of control, who should have absolute authority in the matter.

Provision should be made for the periodic review of the progress of each offender under training with a view to his parole, subsequent licence, and final discharge. Local after-care committees should be organised as part of the general scheme of communal supervision.

To enable the courts to effect correct commitments *in the first instance*, the services of specially trained social workers, psychiatrists, and physicians should be available for their consultation, and coöperation should also be established between the courts and the early treatment centres under the Mental Treatment Act.

PHILOSOPHY AND AFFAIRS.

FROM a group of distinguished signatories we have received the following letter:—

"In the multitude of causes that appeal to the British public, philosophy might seem to be the last that has a claim on the attention of practical men. But it is not difficult in the present disorganisation of beliefs in fundamental principles that is manifest in every department of life to see the need of a cultivation of systematic thought that has the most intimate bearing upon practice. We venture, therefore, to invite public attention to the work of the British Institute of Philosophy.

"Founded in 1925, with the late Lord Balfour as its president, the institute has now a membership of over 1400, which includes in addition to the general body of members, almost all the representative philosophers in Great Britain as well as many distinguished scientists. The institute publishes a quarterly review, *Philosophy*; it holds courses of lectures and organises reading circles; it arranges for the delivery of addresses by men of authority. In addition to the work which is being done in London, there are active local centres in Bangor, Cardiff, Liverpool, Newcastle and Durham, and Sheffield.

"The institute is anxious that its work should be more generally known, in order that an enlarged membership may open to a wider public an opportunity to study the principles that underlie human experience and action in science, art, politics, morals, and religion. Those of your readers who would desire to become members of the institute (the subscription is one guinea including the quarterly review), or to obtain further information with regard to it, are invited to communicate with the Director of Studies at the rooms of the institute in University Hall, 14, Gordon-square, London, W.C. 1."

This invitation is signed by Prof. S. Alexander, O.M., Sir Arthur Eddington, F.R.S., the Archbishop of York, the Dean of St. Paul's, Prof. A. D. Lindsay, Sir Oliver Lodge, F.R.S., Prof. J. H. Muirhead, Earl Russell, F.R.S., Lord Rutherford, O.M., Sir Herbert Samuel, and Prof. W. R. Sorley.

BRITISH MILK INDUSTRY.

AT Guildford, at the last annual general meeting of the Cow and Gate Co., Ltd., Mr. H. J. Suenson-Taylor, the chairman of the company, made some interesting remarks referring to a recent statement of the Minister of Agriculture to the effect that public money could only be spent on an inquiry into the milk industry of the country when there was a definite indication that the industry was prepared to go forward. He added that, if those interested in milk production were going to ask for protection against certain forms of milk coming into the country, they must give indications that they would be able to replace these products. Mr. Suenson-Taylor took up the challenge by saying that, as far as his company was concerned, it was ready to extend factories and plant in response to assurance of reasonable legislation designed to restrict imports brought into the country at less than the cost of home production and transport charges. The company obtains great public support and the statement by its chairman that the success achieved accrues to the public benefit is justified by the standard of its productions.

ACUTE ILLNESS DURING PREGNANCY.

Prof. J. A. NIXON writes from the Department of Medicine of the University of Bristol:—

"I am trying to collect information as to the effects of acute illness during pregnancy upon the child, should it be born alive and survive its birth. *I should be very much obliged to any of your readers* who can send me any data, particularly with reference to developmental defects either physical or mental."

PEPSIN TREATMENT OF PEPTIC ULCER.

Messrs. Paines and Byrne, Ltd., of 31, Southampton-street, Fitzroy-square, London, W.1, inform us *that* they have a stock of the pepsin injections mentioned by Prof. K. Glaessner, of Vienna, in his paper in THE LANCET of Jan. 9th.

SOCIETY OF MEDICAL OFFICERS OF HEALTH: *Fever Hospital Services Group.*—A meeting of this group was held in London on Jan. 29th at which Dr. E. W. Goodall, the President, delivered a presidential address on Some Prebacteriological Views on Infectious Disease. Confining his attention chiefly to the period immediately preceding the inception of the germ theory of disease—that is about a century ago—he pointed out that Fracastor's views on the nature of contagion had been forgotten, and he quoted from various authors to show that few believed in the contagium vivum, and that the doctrine of spontaneous generation was widely accepted. The occurrence of epidemics was attributed to miasms, and contagion was held to play no or only a secondary part in their production. He dealt lastly with the classification and nomenclature of the infectious diseases, drawing attention to the differences between old and modern methods and giving an outline of the growth in knowledge of the different disorders which were included at one time under the term "*continued* fever." Dr. E. H. R. Harries proposed and Dr. Sage, Sutherland, seconded a vote of thanks to Dr. Goodall.

ADDRESSES AND ORIGINAL ARTICLES

THE NATURAL HISTORY OF DUODENAL ULCER.*

BY JOHN A. RYLE, M.D., F.R.C.P. LOND.,
PHYSICIAN TO GUY'S HOSPITAL.

THE subject of this lecture is one which has engaged the thoughts of physicians and surgeons for a quarter of a century, but which still supplies them with unsettled problems. Mindful of the title of this office and of my inability to expound the anatomical or the surgical precepts of John Hunter, I have felt that I might at least, in humble fashion, demonstrate my devotion to the observational method of John Hunter the naturalist. The physician is or should be, above all, a student of the natural origins, associations, and sequences of disease, and in this capacity he can best render his contribution to prognosis and to therapeutic principle.

During the past 12 years I have had considerable opportunities of studying the problems of duodenal ulcer both at hospital and in the course of private practice. My close association with Dr. A. F. Hurst and his thorough methods of inquiry has furnished a constant stimulus, and I have been indebted to my friends, the surgeons and the radiologists for much instruction. Increasing familiarity with the disease has bred anything but contempt. Each year there have been new observations to record and new explanations to seek. The vast fund of information in the literature and the steady output of special researches on the subject notwithstanding, a broad review of the natural history of ulcus duodeni is, I believe, justified by the following four considerations:—

1. Duodenal ulcer is a prevalent disease, and there is evidence (although due allowance must be made for growth and concentration of population and for improvements in diagnosis) that this prevalence waxes rather than wanes under the existing conditions of civilised life.

An inquiry into the admission-rates of some common diseases at Guy's Hospital shows that, on the average, 100 cases of duodenal ulcer are admitted annually—that is to say, about 1 per cent. of all admissions—a figure somewhat less than the admission-rate for tuberculosis (all forms) but greater than that for all the pleurisies and lobar pneumonias combined. In addition, large numbers of cases are treated in the out-patient department. In my private practice, which has a general character—albeit with an abdominal bias—the ten most frequent diagnoses are duodenal ulcer, anxiety state, constipation, cholecystitis and gall-stones, hyperpiesia (with its cardiac and neurological sequels), tuberculosis, anæmia (all forms), migraine, spastic colon, and obesity. Of these, duodenal ulcer heads the list, accounting for approximately 5 per cent. of all my cases.

Wilkie,[1] stressing the steady increase in the cases of perforation at the Royal Infirmary, Edinburgh, in spite of improvements in diagnosis and treatment and a multiplication of the smaller hospitals capable of dealing with these catastrophes, reasonably argues that the total incidence of the disease is rising. At Guy's Hospital the same thing is to be observed. Dividing the period 1910–29 into four five-year periods the admission-rates for perforated duodenal ulcer are as follows:—

1910–1914	.. .. ..	48 cases
1915–1919	(war period) ..	29 ,,
1920–1924	.. .. ..	87 ,,
1925–1929	.. .. ..	115 ,,

A part of this increase may be due to the fact that surgeons have come to observe a better precision in locating ulcers with reference to the pyloric sphincter. The annual total of deaths from duodenal ulcer in England and Wales has almost doubled in the last decade (see below). It seems doubtful whether this increase can be wholly accounted for by such factors as growth of population, improved recognition, and better habits of precision in recording the site of the ulcer. Moreover, the deaths from gastric ulcer have shown a contemporary and parallel rise. In both cases the increase is much more conspicuous in the males.

2. Although the mortality of its most serious complication has been remarkably diminished by surgery duodenal ulcer continues to take its toll and remains, through painful dyspepsia and occasional hæmorrhage, a serious cause of disability and lost efficiency among members and classes of the community often endowed with energy and usefulness above the average and sometimes with outstanding ability.

3. Although of all the dyspeptic disorders duodenal ulcer presents the most clear-cut clinical picture, its leading characters and natural behaviour are not so widely appreciated in the profession as they might be.

Thus the length of time elapsing between first appearance of symptoms and diagnosis is usually to be reckoned in years rather than months. As the prospects of sound healing with a medical régime are best in the early days and diminish with the passage of time (vide Nielsen,[2] whose figures support the common experience of physicians), the prompt recognition of symptoms is an essential contribution to therapeutics. Except in the case of doctors or medical students, I rarely see a case with a history of only weeks or months. Among 184 cases of duodenal ulcer referred to me in which the length of history is recorded, there were only 52 in which this was two years or less. I have notes of 48 cases with histories of ten years and upwards, and of these 17 gave histories of 20 years or more, and a further five had had symptoms for at least 30 years. Among 121 cases (excluding cases of pyloric stenosis) in which the length of time between first symptoms and diagnosis could be roughly computed (all cases diagnosed in less than one year being counted as "immediate") *the average interval was seven years.*

4. Duodenal ulcer has supplied us with a number of problems in ætiology, prognosis, and treatment which are at present only partially solved.

Doubts and difficulties continue to confront us. The wavering from medical to surgical and back to medical opinion and the continued invention of new treatments and operations are eloquent of our uncertainty. Extravagant claims have been made from time to time by protagonists of both the medical and surgical schools. Bacteriology, biochemistry, minute anatomy, and statistical inquiry have, severally and collectively, failed to give the whole answer to our question. We have reached a point at which therapeutic experiment and specialised studies seem no more competent to give help in practice than a general survey of the active disease as it occurs and as it varies in living man.

To achieve such a survey with any completeness and within the compass of a single lecture would be an impossible task. I must therefore content myself with a condensation of experience and must ask to be excused lengthy references to the literature. All that is best of our knowledge of the subject is to be found in Moynihan's "Duodenal Ulcer" and in "Gastric and Duodenal Ulcer" by Hurst and Stewart. To the authors of these classics we must always remain indebted. If my remarks provide some small stimulus to the further pursuit of the old observational method (and without the coöperation of this method experimental medicine can make but a halting advance), and if, in addition, I can adduce reasons for the adoption of a more judicial attitude in arranging the treatment of cases, I shall be well satisfied.

---

* Hunterian lecture delivered before the Royal College of Surgeons of England on Feb. 8th.

I have among my files the notes of upwards of 350 cases interrogated and examined by myself to which the diagnosis of duodenal ulcer is attached. From these I have separated for analysis only those in which the clinical story was confirmed by operation, hæmorrhage (generally melæna), or a reliable radiologist. This series comprises (*a*) 218 cases, of which 24 had proceeded to the development of pyloric stenosis. To these I have added (*b*) 35 cases of anastomotic ulcer, and (*c*) eight cases of other surgical disappointments following gastro-jejunostomy undertaken for the relief of a duodenal ulcer. My mental images are naturally coloured by an equivalent experience of hospital patients drawn from other sections of the community, but I have preferred to employ the material immediately to my hand and upon which all observations were intimate and personal.

The Origins of Duodenal Ulcer.

CONSTITUTION.

Wherein should we seek the beginnings of a disease which tends strongly to relapse or chronicity and which has no basis in contagion or epidemic causes? Clearly, I think, in the peculiarities and antecedents of its victims or in their habits and environment. Preoccupied with the lesion and with hypotheses as to its mode of initiation and perpetuation by local bacterial and chemical action we have too long delayed our study of the soil in which it thrives. We have but to observe in sufficient number our patients as they come before us to appreciate that we are here confronted with distinctive human types or constitutions. Within these constitutions we may already discern certain physical, biochemical, and psychological variants which between them supply what we may call the "ulcer diathesis." Thus, if our notes are sufficiently descriptive, we find again and again that our patients are delineated as "lean and nervous" men, often tense and muscular and with brisk mental and physical reactions, or, alternatively, as robust and energetic and, when free from symptoms, of strikingly healthy appearance. There are even physiognomical characters which may impel us to hazard the diagnosis before the history is taken, but, as the disease itself may put a stamp upon the features, we cannot here be sure that we are concerned with heritable variations. The epigastric angle is commonly wide, and the observations of Faber[3] have enabled us to correlate this feature with the short, high, "steerhorn" stomach of the radiologist. Moody, Van Nuys, and Chamberlain[4] find this type of stomach more common in the male sex. Campbell and Conybeare[5] have also associated this type of stomach with broad athletic men on the one hand and with hyperchlorhydria on the other. Izod Bennett[6] and I earlier reported hyperchlorhydric curves in 8 per cent. of healthy male students. Psychologically these folk are energetic, restless, conscientious, intent on their projects, and not seldom given to anxiety of mind. If engaged in business their city lunch is an occasion not for respite and digestion, but for more business. Recognition of these facts is essential to a proper understanding of the disease and to the handling of cases. No disease, however, should be summarily ascribed in any part to constitutional causes unless we can also demonstrate that it exhibits a familial tendency. Other chronic maladies like gout, asthma, and epilepsy have long been accepted as having some basis in constitutional causes and provide positive family histories in approximately 25 per cent. of cases. Occasional reports on the familial tendency of ulcer had appeared previously, but it was not until 1921 that Hurst,[7, 8] who is so largely responsible for our reawakened interest in the constitutional factor, laid emphasis upon the real importance of inheritance in this disease. In his paper bearing on the subject he quoted among others three family histories which had then come to my notice, including one in which three brothers were operated on for duodenal ulcer and a sister for gastric ulcer. In my present series (*a*) there were 23 instances (10 per cent.) in which a near relative—i.e., parent, child, brother, sister, aunt, uncle, or first cousin—was recorded as having had a duodenal ulcer. In one instance the father of the patient, two uncles, and one cousin, and in another a sister and two maternal cousins had been afflicted. Histories of "dyspepsia" in near relatives are also common. If allowance be made for the infrequent recognition of duodenal ulcer as a cause of dyspepsia in the last and preceding generations, the frequency with which the diagnosis is missed at the present day, the customary inattention to the family history of a disease until its importance becomes widely accepted, and the difficulty always experienced in collecting and recording medical pedigrees, it seems probable that the actual incidence of positive family histories in duodenal ulcer would prove to be higher than these figures indicate.

SEX, AGE, AND OCCUPATION.

Sex.—The well-recognised preponderance of male over female cases (four to one in the present series) must also have some bearing on ætiology. The broad epigastric angle and steerhorn stomach are commoner in the male sex. The male of the type described spends his energies freely, often bolts or misses meals, often smokes excessively, and generally lacks the aptitude or opportunity for quiet in his life which falls more frequently to the lot of womankind.

Age.—The age-incidence of the disease is also instructive. Roughly half the cases are between the ages of 30 and 50, that is to say, within the period of life when work and worry most predominate. Duodenal ulcer is rare in childhood and, in fact, until after puberty, although occasional boyhood cases are to be found in any long series. It is rare for symptoms to make their first appearance after the sixth decade, although recurrences then and even into the seventies and eighties are not infrequent. The average age in my series at the time of consultation (excluding cases of pyloric stenosis) was 47 years. The youngest patient was aged 19, the oldest 83. The youngest calculated age of onset was 9 years, and there were others as young as 12 and 15. Positive family histories, as we should anticipate, appear to be more frequent in the youthful group.

Occupation.—The influence of occupation is hard to assess. No figures, for instance, are available for comparing the incidence of the disease in urban and agricultural communities. On a retrospect of experience it is difficult to avoid the conclusion that the life and occupations of the city are rather more productive of the disease. Among 94 cases in which the profession is recorded I find 28 doctors, 22 business men and lawyers, 13 officers of the Army, Navy, and

Air Force, 7 dentists, and 24 in other walks of professional life. Doctors and members of the fighting forces also appear to show a special liability according to Hurst's figures from New Lodge Clinic.[8] The missed and bolted meals, and the cares which come to interrupt the smooth course of his digestion, might well be advanced in part explanation of the medical man's apparent predisposition to the disease. Its occurrence in the Services is merely a reminder that the disease is one of robust or active rather than frail or indolent constitutions. Lord Moynihan[9] has recently referred to his experience of cases in athletes of the first rank.

OTHER ÆTIOLOGICAL FACTORS.

Tobacco.—Smoking had been indulged in by the men almost invariably and sometimes in great excess, but, although medical and surgical opinion unite in opposing the free use of tobacco by ulcer victims, and many patients appreciate that they are better without it, or even that it may aggravate symptoms, it is difficult to obtain concise proofs with regard to the part which this habit plays in determining the arrival or perpetuation of symptoms or the different incidence of duodenal ulcer in the two sexes.

Focal Sepsis.—Although it is a reasonable part of treatment to eradicate focal sepsis, and although the teeth or the appendix can often be shown to be unhealthy, the actual contribution of cryptic infections is still difficult to assess. Dental, tonsillar, and sinus infections are not necessarily followed by duodenal ulceration, even in persons predisposed by constitution or habits of life. Furthermore, duodenal ulcer may develop in patients in whom no focus can be found or who have long since been deprived of their teeth or vermiform appendix.

Environment.—I have referred to the possibility of a higher incidence of duodenal ulcer under the conditions of life in cities. With others I have also been struck by the promptly beneficent influence of a healthy out-of-door life on the active symptoms of the disease. A country holiday will frequently cut short an attack. Nervous influences play their part, for pain may cease on the first day of the holiday. One patient of mine could spend weeks ski-ing in the Austrian Alps, living on black bread and beer, without symptoms, but would relapse in his English home where his diet was carefully arranged. But more impressive than such isolated cases has been the story, repeated to me on several occasions, that men with duodenal ulcer, who were dyspeptics before their military service and again on their return to office life, were entirely free from symptoms under the hard physical conditions of active service abroad during the war.

Climate may also play some part. I have had patients who were free from symptoms in India but afflicted when at home, and Major E. B. Marsh, who made a particular study of duodenal ulcer among the troops at Aldershot, where he found it prevalent, later wrote to me from India to report that in 22 months in the East among British troops, differing only in that they were slightly older than the home troops, he had not seen a single proven case of ulcer.

Season, as Moynihan[10] showed long since, undoubtedly influences the fluctuations of the disease in the individual, winter, or autumn and spring recurrences being commonly described. Recurrences at these seasons or "in cold weather" were specifically entered in my notes in 25 cases (12 per cent.) of the duodenal ulcer series (*a*). Raw east winds are particularly obnoxious to sufferers from duodenal ulcer. Seasonal infections may be a factor, but the majority of patients do not remark on this association.

Mental States.—A restless stomach accompanies a restless mind. In many cases anxiety and mental conflict seem to play a part in the aggravation of symptoms. In a minority of cases (although it be beyond proof) it is tempting to wonder whether the disease would have developed in the absence of psychological turmoil.

Ætiological studies are thus shown to be of some importance, and if we can cast our vision forwards to a time in which we shall be more concerned with the prevention than with the cure of chronic diseases of this class it is clear that our method will find its basis quite as much in intimate studies of constitution, habits of life and environment, as in the refinements of chemistry, bacteriology, and animal experiment. In our choice of treatment of the active disease we must also remain attentive to these elements in its natural history, remembering that the success of therapeutic experiment in the long run depends even more upon knowledge and judgment than upon technique.

The Course of Duodenal Ulcer.

I have referred to the long interval which commonly elapses between first symptoms and diagnosis. The chief reason for this is to be found in the natural tendency to spontaneous remissions of symptoms. Patients and doctors alike in the first attack, delighted by the quick response to dietary care or "a bottle of bismuth," with disappearance of all pain within a period of two or three weeks or less, are lulled into an attitude of false security and deem the "bout of indigestion" past and done with. As Moynihan and others have clearly proclaimed, this behaviour is characteristic of the disease. If we are to judge by the early clinical course of duodenal ulcer (for symptoms surely bear some relationship to "activity") there must be repeated attempts at natural healing, and this is a particular justification for medical measures at this stage. That spontaneous healing occurs is evident from the scars found in the course of routine post-mortem work. The first attacks may last no more than ten days and rarely more than three or four weeks, and they may be followed by free intervals of enjoyable health, with ability to eat all foods, enduring for six months or longer. The man who starts his illness with a melæna is really a lucky man, for by this means his diagnosis is declared and early and strict treatment instituted. Many patients go free all the summer months and suffer relapses between October and March. With the passage of years the bouts of dyspepsia become more prolonged and frequent. And so the disease may drag on intermittently for five, ten, or even twenty years, with or without distinctive complications and often, in the latter event, without a diagnosis.

Hæmorrhage occurred at one stage or another in rather less than 40 per cent. of this series (*a*), but it should be recalled that many cases unconfirmed by operation, X rays, or hæmorrhage were excluded, so that the figure is clearly too high. Most authors of experience record hæmorrhage as occurring in approximately 25 per cent. of cases. Allowing for the many "missed" dyspeptic cases, all recorded percentage figures for the complications must be accepted as too liberal. Perforation (including "local perforations") occurred in ten cases of the duodenal ulcer series (*a*) and in the anastomotic ulcer series (*b*) (35 cases) in seven cases before and three after operation. These figures give no indication of the actual frequency of perforation. The physician is rarely called to these emergencies. It is, however, a much rarer complication than hæmorrhage. Pyloric stenosis occurred in 24 (11 per cent.) of my cases series (*a*). The serious complication of involvement of the head of the pancreas, with its particular syndrome (to be described later) occurred in 2 per cent. of this series.

Mortality of Duodenal Ulcer.

It is impossible to estimate the death-rate of a disease so widespread and yet so ill-recorded as duodenal ulcer. Even allowing that the majority of deaths among patients of the hospital class occur in hospital we can obtain no accurate measure, for hospitals not only attract the cases of perforation and hæmorrhage in undue proportion, but also admit only the more serious of the dyspeptic cases. In 20 years at Guy's Hospital there have been 153 deaths among cases of duodenal ulcer. Of these, 70 followed perforation, 25 followed hæmorrhage, and the remainder were indexed as due to various secondary complications of perforation or of operation undertaken for the relief of the disease or of its complications, or to intercurrent disease. That is to say, in a hospital admitting about 100 cases a year, about seven or eight cases a year die from all causes. For every one of these 100 cases admitted to the wards there must be several others from the same communities treated as out-patients and in their homes, or remaining undiagnosed and untreated. In general, although its interruptions to health are numerous, the menace to life of a duodenal ulcer is not a very grave one. According to the Registrar-General's returns there were 1140 deaths (male) and 160 deaths (female) from duodenal ulcer in England and Wales during 1930, as compared with 552 (male) and 129 (female) in 1920. These figures are sufficiently arresting, and yet they must represent but a small percentage of the total army of recognised and unrecognised cases.

The Symptoms of Duodenal Ulcer.

Moynihan[10] has rightly insisted on the anamnesis as the main plank in the diagnosis of duodenal ulcer. This should include all proper inquiries into personal and family history, environment, occupation, and habits, for these may serve not only to complete the opinion, but also to balance judgment in therapeutic decisions. But above all our interrogations must deal intimately with subjective phenomena. In the majority of cases it should be possible to arrive at a diagnosis of duodenal ulcer from the history and symptoms alone, and before the physical examination or accessory measures, such as radiology and the test-meal, have been called upon to play their part.

The leading symptom is the pain. It is true that an ulcer may be present to the tune of "wind" or "acid vomiting" and that the patient may deny the occurrence of true pain, but this is not usual. Employing a method of pain-analysis which I have advocated elsewhere we may consider the pain of duodenal ulcer under ten headings having reference to (1) character; (2) severity; (3) situation; (4) *localisation (or extent of diffusion); (5)* paths of reference; (6) duration; (7) frequency; (8) special times of arrival; (9) and (10) aggravating and relieving factors. The character of the pain is described with great consistency as "gnawing" or, alternatively, as "aching" or "like a toothache." There is no intermission, although there may be slight fluctuations while it lasts. It is "wearing" and "worrying" but not so severe, as a rule, as to prohibit work, although it may hamper efficiency and concentration. With the occasional complication of pancreatic erosion it may, however, become very severe and even require morphine for its relief. Its situation is indicated by the patient with the finger-tips in mid-epigastrium or slightly to the right in more chronic cases; it is then generally at a lower level than that indicated by the right subcostal gesture of cholecystitis. It has a precise position and localisation, but in severe, old-standing cases, and especially when flatulence with ærophagy is pronounced, it may "spread" widely into the chest. When the pancreas is involved it "goes through" to the back at the same level and, occupying the region of the twelfth rib (appreciably lower than the subscapular reference of gall-bladder disease), it may even create a suspicion of a right renal lesion. In these cases, too, the anterior pain may be "right subcostal" rather than "epigastric." The pain is absent on waking, and remains in abeyance until some two to two and a half hours after breakfast. Arriving, let us say, at 11.30 A.M. it will persist for an hour or more or until relieved by lunch, but it may return again before tea and agai in the evening. Rearrangements of diet or meal will modify the behaviour of the pain. In cases o long standing a special time of occurrence is 2 A.M. when it wakes from sleep and lingers for an hour o two unless assuaged by food, a warm drink, or medicine It is aggravated by fasting, worry, fatigue, and cold and sometimes by smoking. It is relieved by food drink, warmth, rest, peace of mind, and alkali Delayed pain, first noted in 1828 by Abercrombie, and the hunger-pain with relief by food so clearl portrayed by Moynihan (although they are occasionall due to other causes—i.e., gall-stones, appendiciti gastric ulcer, worry, tobacco-excess, and very rarel carcinoma of the stomach) are thus the outstandin features of the disease.

We must not, however, neglect associated symptom With or without the pain an epigastric "sinkin sensation," which probably represents an exagger tion of the normal gastric phenomena of hunge is often mentioned. It is rare in other dyspepsia Feelings of "flatulence" or of fullness or a "burstin sensation" may accompany or replace the pai In all cases of dyspepsia with pronounced flatulen the time of arrival of the symptom should determined. If this is before meals and food giv ease the possibility of duodenal ulcer (even in th absence of pain) must be seriously considered. Th relief by eructation, and especially that which follow the use of bicarbonate of soda, suggests to the patien and often to his doctor, that the case is "merely o of flatulent dyspepsia," but flatulent dyspepsia mu have a cause, and when the flatulence is rhythmic and at its worst before meals this cause is ofte duodenal ulcer. The gas eructated is odourle except in the presence of pyloric stenosis when may have the taint of sulphuretted hydrogen. Vomi ing has been regarded as a rare symptom in duoden ulcer without stenosis, but this requires qualificatio Vomiting of food is, indeed, exceptional, but an acid watery vomit is common especially with the more chronic ulcers. If later the quantity of this watery vomit increases or *food is mingled with it* cicatricial stenosis should be suspected. Acid eructations which burn the throat and roughen the teeth are the only symptom, in my belief, of hyperchlorhydria and so may occur with duodenal ulcer, but they are not usual. Waterbrash, or the sudden filling of the mouth with tasteless watery saliva, sometimes with accompanying pain in the parotid glands, is more common and so characteristic of duodenal ulcer and so rare in other dyspepsias that it has genuine diagnostic value. One patient spontaneously and aptly described this symptom to me as "a beautiful action of Nature."

Waking, he said, at night with bad pain he would shortly find his mouth filling with water as fast as he could swallow it; as he did so the pain steadily faded away. Heartburn and nausea are not symptomatic of duodenal ulcer. Constipation, especially during the attacks, is a frequent complaint.

Apart from the local symptoms of the disease there are certain general complaints which are very real to the patient and sufficiently rare in other gastric disorders to be of definitive value. I would particularly mention a feeling of physical weakness or exhaustion which is coincidental with the pain and akin to feelings experienced in association with rectal spasm, excessive purgation, or other strong visceral crises. Mental irritability and loss of the power of concentration are also described and are evidence of the powerful nervous influences attendant on a visceral disturbance which carries with it, as well as pain, the psychic and physical phenomena of strong hunger. These symptoms also are relieved by food.

FACTORS WHICH INFLUENCE SEVERITY, CHARACTER, SITUATION OR FOOD RELATIONSHIPS OF THE PAIN.

It should be mentioned, for it is not as widely appreciated as it might be, that the degrees of physical disturbance in duodenal ulcer show wide variations. The physician sees many cases in which the very mildness of the symptoms has led to a postponement of diagnosis. The surgeon, no doubt, sees a higher proportion in which pain is outstanding and severe. The severity of the pain tends to increase with the chronicity of the ulcer. It increases at first with commencing stenosis, but later, as gastric dilatation supervenes upon hypertrophy, pain becomes less obtrusive and vomiting is the leading symptom. When the head of the pancreas is eroded by a posterior ulcer the pain is at times unbearably severe and in the presence of this complication I have seen courageous men reduced to exhaustion and tears. Apart from hæmorrhage it is the only symptom which the physician may be called upon to treat with morphine. It is worthy of note that hæmorrhage may immediately abolish pain. When bleeding is severe, confinement to bed, morphine, and abstention from food and later a strict dietary clearly explain the relief, but even slight and at first unrecognised bleeding with an ambulatory case will have the same effect. In this circumstance a patient who has been suffering dyspeptic pains may actually hold himself better as regards his ulcer and a failure to appreciate the significance of developing weakness and anæmia results. In the presence of early stenosis pain may become more "grinding" or "peristaltic" in quality. The situation of the pain commonly shifts to the right in the case of old-standing and adherent ulcers. The interval between food and pain diminishes in the early stages of pyloric stenosis and may be reduced to one or one and a half instead of the two or three hours previously experienced. It should also, however, be recognised that patients with extreme gastric "hurry" occasionally show a very short food-pain interval. With ulceration involving the head of the pancreas all clear relationship to food tends to disappear and alkalis may cease to be effective.

Objective Signs.

In the absence of pyloric stenosis with gastric dilatation or the rare discovery of a palpable inflammatory tumour it is too widely assumed that duodenal ulcer is a disease without physical signs. If carefully sought for, superficial, or more commonly deep cutaneous soreness, an increased abdominal reflex, muscular guarding, and deep tenderness—all confined to the right upper quadrant of the abdomen—will be found either singly or in various combination in a high proportion of cases. These signs are more likely to be found with anterior ulcers, during stages of activity, and when pain is actually present. They disappear with healing. An increased reflex and muscular guarding are both more common than cutaneous hyperalgesia. Very occasionally a pilomotor reflex (goose-skin) confined to the same area may be observed when eliciting the abdominal reflex. The vasomotor consequences of active pain are sometimes manifest in the facies. Thus near relatives describe pallor or "greyness" coincident with suffering in chronic cases. Phosphaturia is so common in association with active duodenal ulcer that I have come to expect a milky urine at the time of consultation in the majority of cases. How far it is related to the taking of alkalis or not I have been unable to determine. Loss of weight is seldom conspicuous in uncomplicated cases.

Complications and Sequelæ.

Hæmorrhage and perforation, cicatricial stenosis and anchorage of the ulcer-base to the head of the pancreas are the important complications. To these we must add the unsuccessful gastro-jejunostomy which, under modern conditions, has been a sufficiently frequent sequel to justify its inclusion in a study of the natural history of duodenal ulcer, and, in a retrospective way, may even help to illuminate the disease.

With the symptoms of hæmorrhage and perforation I shall not especially concern myself for they are well known. Hæmorrhage, as stated, occurs in about one-quarter of the recognised cases. In many of my cases there was a history of two or more hæmorrhages; 107 patients (series *a* and *b*) between them had 151 hæmorrhages. Two patients, aged 76 and 56, died of gastric uræmia (alkalosis) with coincident hæmorrhage, in one case following an operation. One, aged 56, died of coincident hæmorrhage and cellulitis of the arm. One, aged 36, was transfused on account of a severe hæmorrhage from a chronic ulcer, had an immediate reaction and succumbed. Three cases, aged 76, 72, and 26, died of hæmorrhage alone. The older the patient, the longer the history and the more severe the tale of dyspeptic symptoms, the more seriously should an hæmorrhage be regarded, for the more likely in this event is it that the ulcer is deep and that a large vessel is eroded. In the case of bleeding with slight or recent dyspeptic symptoms or without previous dyspepsia and in young subjects, the prognosis can usually be reassuring. In my solitary fatal case in a young man there was a long history of very severe pain with a posterior reference which had led me, a few days earlier, to a diagnosis of pancreatic erosion. The total mortality from hæmorrhage is small. There were 25 deaths from this cause during 20 years at Guy's Hospital as compared with 128 deaths from other causes. The association of pyrexia with recent hæmorrhage is worthy of mention. As Hurst[8] concludes it is probably due to retention of blood in the bowel, for it subsides when the bowel is clear. In one case of mine, a severe hæmorrhage occurred but without hæmatemesis or melæna. The bowels did not move for several days and the combination of high fever and acute anæmia had, not unnaturally, caused doubts as to the correct opinion.

As indicated no idea of the incidence of perforation can be obtained from this series. There were 10 cases (series *a*), including cases of local perforation which did not lead to immediate operation. Approximately one-fifth of the cases of duodenal ulcer admitted to Guy's Hospital are for a perforation, but clearly this is the complication above all others which necessitates institutional treatment. The likelihood of perforation is greatest in the early stages of the disease and diminishes with the passage of time.

The classical symptoms of established pyloric stenosis (which is generally a sequel of duodenal rather than prepyloric ulceration) include voluminous vomiting of food taken many hours, or even days previously and loss of weight. The late physical signs include a visible stomach "standing out" on the abdominal wall, visible peristaltic movements from left to right and succession splash at a time when the stomach should be empty. It should, however, be possible to diagnose the condition before such striking symptoms and signs appear and chiefly from the past history and an alteration in the time and character of the pain and palpability of the hypertrophied organ. Eructations of sulphuretted hydrogen have been regarded as especially significant of obstruction by a pyloric carcinoma, but I have recorded them more frequently in benign stenosis. They are not necessarily a late manifestation. They were mentioned in eight of my 24 cases. If eggs and protein foods have been excluded from the diet they do not occur.

There is an important, if occasional, syndrome of pyloric stenosis in which general symptoms predominate. This has been described as "gastric uræmia." There were three examples among my 24 cases. The symptoms include drowsiness and irritability or stupor often leading to a fatal coma and are held to be due to an alkalosis such as occurs with the vomiting of high intestinal obstruction or excessive dosage of alkalis. The blood-urea is raised, sometimes markedly so. Vomiting need not necessarily be excessive. Operative risk is increased, and yet if the condition is recognised in time a short-circuit after suitable preparation (including routine lavage) is indicated. Every case of pyloric stenosis should have a blood-urea estimation prior to operation as the operation and anæsthetic may precipitate the symptoms. Treatment with alkalis is contra-indicated in the presence of organic stenosis and renal deficiency. There were no cases of tetany in this series. I have encountered altogether five cases of "gastric uræmia" complicating duodenal or pre-pyloric ulceration. Four ended fatally, and in two the diagnosis was only made at necropsy. The third patient, an elderly subject, who had previously undergone prostatectomy, was also bleeding and was too ill to warrant operation. The fourth was noticed to be mentally peculiar before an operation undertaken for pyloric stenosis and was anæmic from slight hæmorrhage; the true cause of the mental change was overlooked, he became comatose and died shortly after the operation. The fifth case showed no symptoms until after the operation but recovered.

A case of pyloric stenosis with "gastric uræmia" (alkalosis).—A man, aged 51 (sent by Dr. Bernard Haigh), had had "stomach trouble" all his life and was treated medically for duodenal ulcer 20 years previously. Eight years previously he was operated on for a perforated duodenal ulcer, but had never been really well since. He complained of hunger-pain, but had also started voluminous vomiting of acid-fluid with a little food. I noted visible peristalsis. His blood pressure was 200/120; the urine occasionally contained a trace of albumin. After confirmation of the diagnosis in hospital a gastro-jejunostomy was performed by Mr. P. Turner. Almost immediately after the operation he became restless, mentally deranged, and then stuporose. His blood-urea figure was 112 mg. per 100 c.cm., or nearly four times normal. He was treated with sedatives and rectal salines and made a complete recovery.

The average duration of ulcer symptoms in 16 of my cases of pyloric stenosis was 17 years. Only two cases gave histories of five years or less.

INVOLVEMENT OF THE PANCREAS.

The duodenum is doubtless anchored to the pancreas by adhesions in many cases of posterior ulcer. In a small number the base of the ulcer may become more firmly welded to this organ or may actually erode it. In this event a clinical syndrome develops which is characterised by pain of unusual severity, not responding to strict medical treatment and alkalis, and even requiring morphine for its relief. The pain is commonly in the right upper quadrant and referred through to the right loin and may be chiefly felt posteriorly. Biliary and renal calculus are therefore sometimes wrongly diagnosed. Glycosuria occurs in some cases, and I have seen it come and go with the ulcer symptoms. The diagnosis is occasionally missed by expert radiologists in these cases, partly, I believe, because, with firm fixation of the duodenum, the prepyloric antrum is thrust over to the right during peristaltic activity, and so obscures the first part of the duodenum altogether. I have also seen cases in which a posterior adherent duodenal ulcer had escaped detection at operations undertaken for the relief of an ulcer or with a view to discovering the cause of pain.

A case of posterior duodenal ulcer involving the pancreas.—Major A., a fine old soldier, aged 73, suffered for many year from periodic bouts of dyspepsia with pain arriving som hours after food and relieved by it. Later the pain becam greatly intensified and less clearly related to meals. H saw a surgeon who *diagnosed gall-stones and*, in spite of negative cholecystography, operated for gall-stones. Find ing no stones he drained the gall-bladder. Durin convalescence there was melæna on two occasions. Th pain continued as before, and in his worst attacks, whic took place at night, was sometimes so severe as to make hi weep; it was accompanied by involuntary tremors an *shivering. I saw him in pain and it* was a pitiful spectacl The pain was referred to the level of the eleventh an twelfth ribs on the right side posteriorly and there wa guarding with tenderness over the right upper rectus. diagnosed "posterior duodenal ulcer involving the pancreas. The radiologist reported "appearances strongly indicati of an ulcer of the stomach about half-way between th cardia and the pylorus." Mr. L. Bromley operated an found no gastric lesion but a posterior duodenal ulcer firml welded to the head of the pancreas. A gastro-jejunostom was performed and all symptoms were completely relieve

ANASTOMOTIC ULCER.

For every ten cases of duodenal ulcer referred me I see one case of anastomotic ulcer. This gives indication of the frequency of this sequel, for it evident that surgical "failures" find their way the physician just as medical "failures" find the way to the surgeon. The sequel, however, is serious one and sufficiently common to justify caref inquiry into its causes and the greatest caution in t selection of cases for a gastro-jejunostomy.

The development of ulceration at or near the ston has been variously attributed to faulty techniqu unabsorbable sutures, the failure to eradicate foc sepsis, and neglect of appropriate after-care. My ow experience suggests that more important than a of these are a faulty judgment in the selection of cas for operation and the presence of a strong constit tional predisposition. There was a positive fami history in seven out of my 35 cases of anastomot ulcer (*b*), twice the rate of incidence in the duoden ulcer series (*a*). The age at onset of the ulcer-sym toms for which the operation was undertaken w under 20 years in six cases and in three of these the was a positive family history. Early appearance a chronic disease more usual in later decades shou always suggest constitutional predisposition. I ha notes of two cases of anastomotic ulcer in which had myself advised the short-circuit. In the fir the patient's father had had ulcer symptoms, althou ulcer was never definitely diagnosed, and the patient himself started life with congenital pyloric stenosis. The second patient was a highly nervous and restless man, continually preoccupied with financial cares. His symptoms had recurred in spite of strict medical treatment. He developed vicious cycle vomiting soon after the operation together with signs of a local peritonitis. Unsuitable temperament and technical flaw here conspired to bring about the bad result.

In 12 cases the symptoms of duodenal ulcer had been present for only a year or less before the operation, and in four others for two or three years only. In six cases there had been symptoms for ten years or more. The remainder were of intermediate or indeterminate duration. It is difficult to avoid the impression (which these records and my hospital experience support) that short-circuits in the case of young persons and short histories are unsound. It is clear enough that the conditions in either case are remotely removed from those which originally justified the operation—namely, an established obstructive lesion.

In 12 cases of anastomotic ulcer there was a history of hæmorrhage prior to the operation and in nine of these the operation was apparently undertaken largely on account of this symptom. Of the 12 cases which had bled before operation eight bled again after it. Of 23 cases which had not bled before operation ten bled subsequently. On the experience of these cases and hospital work I incline to the view that hæmorrhage should not be regarded in itself as an indication for gastro-jejunostomy. Seven cases of anastomotic ulcer gave a history of perforation before operation. Three of these perforated again afterwards.

Recurrence of ulcer symptoms was noted in a year or less in 19 cases; in two years in 2 cases; in three years in 3 cases; in four years in 1 case; in five years in 2 cases; in six years in 1 case; in seven years in 1 case; in nine years in 2 cases. In four cases the interval was not recorded.

The symptoms of anastomotic ulcer are very similar to those of the original duodenal ulcer. There is hunger-pain with more or less relief by food. Both immediate and lasting relief of symptoms, however, even with the strictest medical care, is much less certainly attained than in the case of duodenal ulcer. Furthermore, pain and distress tend to be more severe and lasting. Hæmorrhage may occur without premonitory pain. The most constant physical sign is a point of tenderness just above and to the left of the navel. Anastomotic ulcers are liable to the same leading complications as duodenal ulcer—namely, hæmorrhage, perforation, and stenosis. The most wretched and often fatal complication is a gastro-jejuno-colic fistula of which the symptoms are pain, eructation of "bowel-wind," or even vomiting of fæces, diarrhœa, anæmia, and emaciation. Fortunately it is rare. I have had two cases under my care in hospital but none in private practice. Hamilton Fairley and Kilner have recently reported on cases showing fatty diarrhœa with a megalocytic anæmia.[12]

OTHER COMPLICATIONS OF THE SHORT-CIRCUIT.

The most important remaining complication is "vicious cycle vomiting," which is characterised by attacks of copious bilious vomiting at irregular intervals with or without pain. The "dumping stoma," in which the common complaint is of a fullness and discomfort around and below the navel developing soon after meals and due to rapid over-filling of the small gut, is inconvenient but less crippling.

THE PROSPECTS OF OTHER OPERATIONS AND MEDICAL TREATMENT.

It is too early to assess the later results of alternative operations such as gastro-duodenostomy, resection, and excision. Only after some 20 years are we learning to view in correct perspective the advantages and disadvantages of gastro-jejunostomy, and if we are wise we shall not too trustfully accept the promises made on behalf of the newer experiments. That they do not always succeed is already apparent. That they will often fail in the presence of strong constitutional predisposition or with *injudicious* selection of cases seems to me probable. Medical treatment carried out for a sufficient length of time, at rest and in accordance with physiological principles and with proper control and careful subsequent "handling," remains our only alternative. Here the best results are naturally obtained with early cases, and the onus lies upon those first responsible for diagnosis. With ulcers of long standing there is often grateful relief, but there are limits to lasting success, extravagant claims are not justified, and the same judicial care must be employed in the selection of cases. But, whereas a surgical failure often leaves the patient in far worse plight than before, the same cannot be said of medical failures. Surgical treatment has been claimed as an insurance against grave complications, such as perforation and hæmorrhage, but the study of post-operative histories shows this insurance to be of limited reliability.

Conclusion.

The naturalist customarily pursues his task for his own instruction and intellectual pleasure and with a view to enlarging the general stores of knowledge. The physician, as naturalist, is actuated by the same motives and, in addition, by the desire to improve treatment for humane ends. It is necessary, therefore, in stating my conclusions, to indicate anything of practical utility which may be held to emerge from a review of the natural history of duodenal ulcer in all its stages. What we chiefly need in practice to-day is some surer guidance in the grouping and management of cases. My present policy, based on experience, of which I have here given a partial account, is to advise gastro-jejunostomy in cases of pyloric stenosis; in cases of long-standing duodenal ulcer in which clinical history, X rays, and test-meal proclaim gross scarring or anchorage and a tendency to slow transit of food without serious stasis, and in which there has been recurrence in spite of one or more strict courses of medical treatment; in cases presenting the syndrome of anchorage to or erosion of the pancreas; and in cases of concomitant duodenal ulcer and duodenal ileus, where, again, there is an obstructive factor at work obviating sound healing by mechanical unrest and increasing the likelihood of perforation by increased intraduodenal pressure (as I have once successfully foretold).[13] My policy is to oppose surgical treatment in youthful cases; in non-obstructive cases with short histories and adverse pedigrees or not previously accorded a strict medical treatment; in cases with recent hæmorrhage, lacking other indications; and in cases in which X ray and test-meal show gastric "hurry," for here to accelerate emptying still further and to attempt an anastomosis in the presence of exaggerated motor and chemical unrest is to create just those conditions which may be held to favour secondary ulceration. Highly nervous individuals and elderly subjects should often be deemed unsuitable for surgery, even when the only alternative is continuous medical and dietary care. Economic and environmental factors must at times compel a modification of general policy. Surgical treatment should always be followed by a period of strict medical treatment and proper precautions thereafter. Psychological as well as physical requirements must be carefully studied.

All surgeons and physicians who undertake the treatment of this troublesome disease must endeavour to preserve the studious attitude, not lightly accepting opinion or submitting to the bias of their craft, and remembering always that they are not, in fact, concerned with duodenal ulcer the lesion, but with duodenal ulcer the disease, as it occurs and as it varies in individuals of special type and temper and differing daily circumstance. In each case, briefly, judgment must be based, not upon the presence of an ulcer, but upon a proper understanding of the whole patient and the whole disease.

As I have sought to show, duodenal ulcer has general effects on the body and the mind as well as general causes in them, and no effect or cause can be neglected.

In a restless and fretful age which has largely lost the old simplicities of diet and conduct the most important contribution which we can make to the prophylaxis of duodenal ulcer is to furnish, as opportunity arises, sensible instructions to the community (and particularly to such families or individuals as manifest a constitutional or occupational predisposition to the disease) with regard to the evils of missed and bolted meals, of excessive smoking, and of the prevalent habit of attempting to combine the process of digestion with anxiety and affairs. It is not extravagant to suppose that a cup of hot milk at 11 A.M. and bedtime would save many a harassed doctor or business man endowed with the diathesis from developing the disease.

The most important contribution which we can make to the therapeutics of duodenal ulcer is, by observing subjective symptoms, to ensure much earlier diagnosis, and, by observing the entire disease and the qualities of its victims, to achieve a wiser balance in our choice of method.

It is, I believe, a just criticism of surgery and medicine in the present era that they have concentrated on parts to the exclusion of the whole and on technique to the exclusion of philosophy. In duodenal ulcer no less than in many other maladies, we have come to rely upon too narrow a pathology. In our therapeutic quests we have been too little observant of physiological principle. We are all compelled by the magnitude of our subject to be something of specialists, but this should not necessitate an abandonment of that naturalistic outlook which marked the achievement of our old preceptors from Hippocrates to Hunter.

I am indebted to Mr. H. L. Eason, superintendent of Guy's Hospital, for access to the hospital records and to Mr. J. F. Mackridge for making the necessary extracts from these records.

TWO CASES OF
LYMPHOGRANULOMATOSIS MALIGNA,
ONE WITH INVOLVEMENT OF THE VERTEBRAL PERIOSTEUM.

BY DOROTHY C. HARE, C.B.E., M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL FREE HOSPITAL, AND ASSISTANT PHYSICIAN TO THE ELIZABETH GARRETT ANDERSON HOSPITAL, LONDON;

AND

ELIZABETH H. LEPPER, O.B.E., M.B. LOND.,
PATHOLOGIST TO THE ELIZABETH GARRETT ANDERSON HOSPITAL.

With a commentary by

F. PARKES WEBER, M.D. CAMB., F.R.C.P. LOND.

CASE 1. *Lymphogranulomatosis maligna with extension to the spinal canal.*—The patient, a married woman aged 31, was in good health until 14 months before her death. Her illness began with "influenza," cough, and general pruritus, and she was admitted to Guy's Hospital, where glandular enlargement was found and a diagnosis of Hodgkin's disease with pulmonary tuberculosis was made. After six months the glands began to enlarge rapidly, and later she was admitted to the East Anglian Sanatorium, under the care of Dr. Jane Walker, and transferred to the Elizabeth Garrett Anderson Hospital, under D. C. H.

Past history.—She had noticed a small gland on the right side of the neck in 1926, but this had soon disappeared. She had probably contracted phthisis from her husband who died in 1925 of that disease.

Symptoms and clinical signs (September, 1930).—She complained chiefly of severe pains down the arms, and o pruritus; she became dyspnœic on slight exertion. The cervical glands formed a massive collar completely deforming the neck and extending downwards under the clavicles the axillary glands were enlarged, but no enlarged gland were detected elsewhere. A gland removed by biopsy showed typical lymphogranulomatosis maligna. The splee was not palpable and the liver not enlarged. There wa weakness and muscular wasting of the arms and hands the reflexes were retained, and there was no sensory change the lower limbs and sphincters were not affected. Ther was a paroxysmal cough and pain in the chest, the sputum contained tubercle bacilli, there was extensive dullness a both apices, and crepitations on the left side. There wa continuous, irregular swinging fever up to 101° F. Nothin abnormal was noted on examination of the other systems Radiographic examination showed enlargement of th intrathoracic glands with pressure on the trachea. Wassermann and sigma reactions were negative.

A *diagnosis* of lymphogranulomatosis maligna wit involvement of the vertebral periosteum was made b Dr. Parkes Weber, who saw the case in consultation.

Course of illness.—Treatment was given by X rays ove the right side of the neck with a view to relieving th pressure pains; no definite change in the glands was noted but the pain was distinctly lessened. The effect of th treatment on the lymphocyte count is shown in the Table The patient became gradually weaker and died on Dec. 1st 1930. Autopsy was performed on the same day.

Post-mortem report (E. H. L.).—Lymphatic glands an metastatic growths. Very numerous enlarged glands ar present on both sides of the neck and in the axillæ, th glands round the lower jaw are discrete, and shell out a the connective tissue is incised; those in the lower par of the neck are matted together and form dense masses the adjacent connective tissue is very œdematous. These glands have to be cut away from the periosteum, to which they are adherent on the anterior and lateral aspects of th lower cervical and upper dorsal vertebræ. In the second third, and fourth intercostal spaces on the right side ar small white nodules of growth lying beneath the pleura close to the spine. On the dorsal aspect of the thorax nodule of growth is present embedded in the muscle betwee the spine and the scapula; the nodule measures $1\frac{1}{2} \times \frac{3}{4} \times \frac{3}{4}$ in On removing the spinous processes a sheet of growth i exposed in the spinal canal, coming upwards on eac side of the dura and almost meeting in the mid-line on th

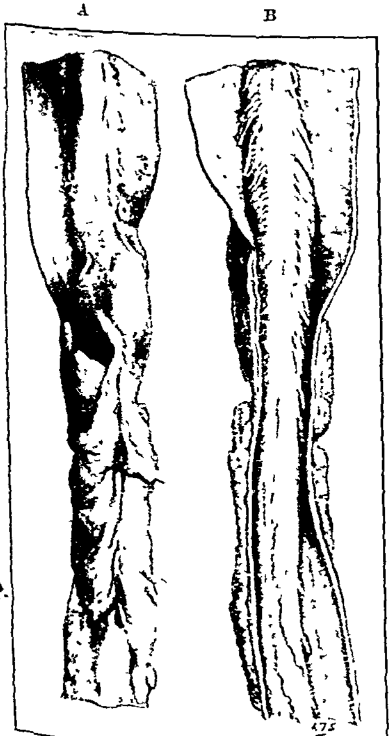
dorsal aspect of the cord. It extends for 5 inches from C. 7 above to D. 5 below. It is infiltrating the fatty tissue in the canal and the periosteum, and involves the bone in the region of the fourth and fifth dorsal spines; it extends round the anterior aspect of the canal and passes through the intervertebral foramina with the nerve roots; it is densely adherent to the periosteum. The cord is œdematous but firm. In the abdominal cavity the lymphatic glands are moderately enlarged; there is no extension of growth from the aortic glands to the periosteum of the spine.

The spleen weighs 10½ oz.; on section it shows several large, firm, yellowish-white nodules from 1 to 2 in. in diameter. The nodules are veined with brown pigment; the intervening tissue appears normal. Liver, kidneys, suprarenals, and pancreas appear normal. There is no enlargement of lymphoid follicles in the alimentary canal. The right pleural cavity contains two pints of muco-pus; there are extensive tuberculous lesions in both upper lobes; the glands are enlarged at both hila.

Histological appearances.—In the large glands the normal structure has entirely disappeared; there are thick strands of fibrous tissue enclosing islands composed of Sternberg cells, lymphocytes, polymorphonuclear and eosinophil leucocytes, and plasma cells; areas of necrosis are present. Localised nodules of typical lymphogranulomatous tissue are present in the spleen, the nodules are surrounded by fibrous tissue, in the outer layer of which is a deposit of brown pigment giving the Prussian-blue reaction; the splenic tissue between the nodules appears normal. A section from the posterior aspect of the dura where the growth is infiltrating the laminæ shows the typical appearances of lymphogranulomatosis. A section from the anterior aspect of the dura is composed almost entirely of small cells with round, deeply staining nuclei arranged in groups in a somewhat hyaline connective tissue stroma. A very few typical Sternberg cells can be found in some places, but plasma cells and polymorphonuclear cells are absent. The appearances resemble an endothelioma. A section of a nodule from an intercostal space, however, showed a combination of these appearances, so that a diagnosis of endothelioma could be excluded, and the common origin of the morbid process established.

The liver, kidneys, suprarenals, and pancreas show no changes.

FIG. 1 (Case 1).



Semi diagrammatic drawings of the upper part of the spinal cord, showing the lymphogranulomatous tissue lying *on the external* surface of the dura. A, anterior, and B posterior, aspect. (Drawings by W. Thornton Shiells.)

CASE 2. *Lymphogranulomatosis maligna with predominant lesions in the spleen and alimentary canal.*—The patient was a married woman, aged 48. She first attended the Elizabeth Garrett Anderson Hospital in 1923 for chronic indigestion, and two years later was admitted for a large hæmatemesis, from which she made a good recovery. Enlargement of lymphatic glands occurred in 1924 in the neighbourhood of the right parotid; these were removed in 1924 and again in 1925; there was no further recurrence in this situation; a small mass was removed from the left posterior triangle in 1929. No enlargement of glands in other situations and no enlargement of the spleen was reported at this time. In January, 1930, considerable splenic enlargement was present, but the general health was fairly good. In July she was admitted to the hospital. She complained of severe epigastric pain, aggravated by the taking of food; the tongue was sore.

Examination.—She was pale and thin, and the spleen formed a prominence on the left side of the abdomen, the lower pole being 1½ in. below the umbilicus; the liver was slightly enlarged. The glands were palpable in the neck, axillæ, and groins, but appeared to be normal. There was no pruritus. The heart, lungs, and nervous system were normal.

Special investigations.—A fractional test-meal on July 24th showed complete achlorhydria. A blood count on July 21st showed 40 per cent. hæmoglobin; a colour-index of 0·5; 4·65 million red cells; and 3500 white cells per c.mm. Another on August 25th showed hæmoglobin percentage of 60; a colour-index of 0·7; 4·98 million red cells; and 4400 white cells per c.mm. The differential white cell count was: polymorphonuclears, 77·5; lymphocytes, 9·5; hyalines, 8·5; eosinophils, 4·0; and basophils, 0·5 per cent. The red cell fragility was normal; the van den Bergh indirect reaction was positive; small amounts of urobilinogen were present in the urine. The Wassermann and sigma reactions were negative.

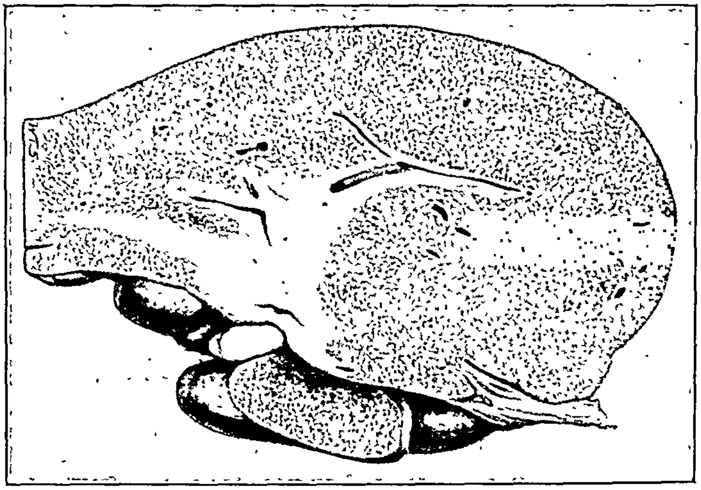
Histological examination of glands removed by operation in 1925 and 1929 (E. H. L.).—The largest and smallest glands all show the same appearances. No normal gland structure remains: it is replaced by small closely packed cells having round or oval nuclei. There is no evidence of active cell division. There is some increase in the endothelial cells, but no typical Sternberg cells and no eosinophil cells are present. There are a few very small areas of necrosis in the larger glands.

Clinical diagnosis.—This was a matter of great difficulty, as the glands removed by biopsy gave no clear histological picture. The diagnoses considered were splenic anæmia, tuberculosis, and Hodgkin's disease. Dr. Parkes Weber, who saw the case in consultation, was of opinion that the balance of evidence was in favour of the last diagnosis. The presence of achlorhydria is of interest, but it was probably secondary to the invasion of the stomach by the disease.

Course of illness.—During 11 weeks in hospital she suffered increasingly from pain, vomiting, and diarrhœa with blood in the vomit and stools. The temperature was irregular, the maximum being 100° F. Death occurred on Oct. 2nd, 1930, and an autopsy was held next day.

Post-mortem report (D. M. Vaux).—There is a chain of glands on both sides of the neck; the largest measures 1 × ½ in. They are discrete, firm, pale, and homogeneous. The axillary glands are moderately enlarged, the bronchial and mediastinal glands very slightly enlarged. There is enlargement of the mesenteric glands and of those along both curvatures of the stomach, round the cœliac axis, and along the whole length of the aorta and iliac vessels; The glands are discrete. There is localised peritonitis in the region of the stomach and spleen, and a small perforation in the middle of the anterior wall of the stomach, shut off by adhesions to the under surface of the liver. The surrounding area of the stomach is covered with blood and is necrotic. There are scattered irregular patches on both anterior and posterior walls of the stomach; the wall is firm and thickened in these areas, and the mucous membrane over them is raised, yellowish, and beginning to ulcerate. The small intestine appears atrophied, Peyer's patches are thickened, and the solitary follicles enlarged. The mucous membrane for half an inch above the ileocæcal valve is thickened and papilliferous. The large intestine throughout shows patches of thickened mucous membrane, especially in the cæcum and proximal end of the appendix.

FIG. 2 (Case 2).



Section of liver, showing fatty infiltration and diffuse white areas of growth round the portal fissure and passing into the liver substance along the lines of the vessels. The section passes through one of the glands in the hilum.

The spleen weighs 33 oz. There is perisplenitis, and the organ is adherent to the stomach and is very firm. The tissue on section is deep red, and closely set in parts with bluish-white nodules of the size of a pin's head; there are also "hard-bake" nodules at or near the surface. The liver is large, pale, and firm; its surface is smooth. On section it shows fatty change and diffuse white areas of growth round the portal fissure and passing into the liver substance along the lines of the vessels. No nodules are seen.

The kidneys, suprarenals, pancreas, and spinal canal are normal.

Histological examination (E. H. L.).—The glands of the neck show complete fibrosis, but no changes are to be detected in the thoracic glands. In the large abdominal glands no normal structure remains. There is a diffuse growth consisting of small cells having round or oval nuclei; there is considerable fibrosis and some necrosis, and a few isolated cells resembling Sternberg cells can be found (after prolonged search three typical multinucleated cells occurring together were discovered). There is marked fibrosis of the spleen, but no necrosis. Amyloid degeneration is present in the walls of the arteries. The changes are very advanced, and no typical lymphogranulomatous structure is found. There is a diffuse infiltration of the liver, spreading from the hilum along the vessels; this consists of small cells with round or oval nuclei and of polymorphonuclear leucocytes, but no Sternberg cells can be found. The infiltration is followed by very marked fibrosis, which has led to small areas of necrosis. There is marked fatty degeneration, but no amyloid change.

In the stomach wall there is marked infiltration of the mucous membrane and submucosa with lymphocytes and polymorphonuclear leucocytes; there is also considerable fibrosis which has obstructed the vessels and caused large areas of necrosis. The cæcum and colon show similar changes.

The marked involvement of the alimentary canal suggested at first that this was a case of lymphosarcoma (Turnbull [1]). A comparison of the histology with that of Case 1, however, leaves little doubt that the two cases are varieties of the same disease, though in Case 2 the lymphocytic type of cell predominates to the exclusion of the typical appearances. In Case 1, tissues were found showing every degree of change, from the typical Sternberg eosinophil granuloma to a growth composed of closely packed small cells exactly similar in appearance to those found in Case 2.

COMMENTARY (F. P. W.).

The first period of the illness in Case 1 appears fairly classical. The occasional association of tuberculosis with lymphogranulomatosis maligna has long been recognised; the cause of the connexion may be explained in different ways in different cases, but it should be remembered that the former disease is common, and the latter not exceedingly rare. Cutaneous pruritus often accompanies lymphogranulomatosis, especially in the earlier stages, sometimes constituting the chief symptom and occasionally leading to a kind of prurigenous dermatitis, and even to a generalised itching erythrodermia. In this case the most remarkable feature was the involvement of the vertebral periosteum, which doubtless caused the pains and paræsthesiæ in the shoulders and upper limbs. These sensory symptoms had led to a diagnosis during life of vertebral periosteal involvement.

In 1923 [2] and in 1926 [3] I described and collected accounts of cases of lymphogranulomatosis complicated by paraplegia or cauda equina symptoms and vertebral involvement, and since then various similar cases have been published.[4] It is clear that in a typical case of lymphogranulomatosis maligna, after the disease has run an ordinary course for a longer or shorter time, the ventral vertebral periosteum may become infiltrated and this infiltration may spread to the periosteum lining the vertebral canal and to the epidural fat, thus giving rise to pains and to paraplegia from the irritation and compression of the nerve roots and spinal cord.

From a necropsy in 1927 [5] it becomes probable that if the spinal column and epidural space were systematically examined in every fatal case of lymphogranulomatosis, even when no nervous symptoms had been recorded during life, lymphogranulomatous infiltration would be found to be more frequent than hitherto suspected.

But why does the vertebral periosteum become infiltrated in some cases, while in most cases it remains uninvolved? I suggest that in this case the periosteum became infiltrated through direct contact with lymphogranulomatous glands in which infiltration of the extracapsular connective tissue was in active progress. Dr. Lepper, in her report, mentions that the diseased lymph glands were matted together and formed dense masses, and had to be cut away from the vertebral periosteum. Looking back on my first case (a young man under hospital treatment from 1919 to 1921), I find that the lymphogranulomatous infiltration of the vertebral periosteum and epidural fat was associated with much involvement of the abdominal lymph glands, notably those about the vertebral column.[6] There can be no doubt that occasionally the lymphogranulomatous process extends beyond the capsules of the glands so as to invade the surrounding extracapsular tissue. O. Naegeli[7] mentions a case which on that account was formerly supposed by Dietrich to be one of lymphosarcoma. In a hospital patient of mine, aged 54 years, who died from lymphogranulomatosis maligna in January, 1915, the abdominal aorta near its bifurcation was found partially embedded in a hard, whitish growth, doubtless formed by the lymphogranulomatous transformation and matting together of para-aortic glands so as to form a firm fibroid mass.

Dr. C. P. Symonds has recently suggested that the lymphogranulomatous process may extend intracranially as it sometimes does into the intervertebral canal.[8]

Case 2 is especially interesting on account of the very extensive involvement of the alimentary canal, and the macroscopically remarkable infiltration of the liver along the lines of the great vessels; and even more so on account of the clinical and histological diagnosis between lymphosarcomatosis and lymphogranulomatosis maligna and the possible relationship between them. It should be noted that lymphosarcoma, as Turnbull[1] sees it, including many cases in which the spleen and liver are affected, is very different in its distribution from lymphosarcoma, as originally described in 1893 by the Viennese pathologist, Kundrat[9]; Naegeli[10] still follows Kundrat in regard to lymphosarcomatosis when he writes: "Wenig und oft gar nicht beteiligt sind Milz und Leber." I would suggest that the term "lymphosarcoma," or, when multiple, "lymphosarcomatosis," includes two diseases:—

(1) The lymphosarcomatosis of Kundrat and Naegeli, which is apparently a neoplastic disease, originating in the lymphoblastic elements of the affected lymphadenoid tissue.

(2) A variety or phase of lymphogranulomatosis maligna or, as we still call it, Hodgkin's disease.

I suggest that Hodgkin's disease originates in the endothelial elements of the reticulo-endothelial portion of the first affected lymphatic glands, or other lymphatic structure, and afterwards tends to become generalised in other regions of the body. Whether it is really a granulomatosis or a neoplastic disease is not yet clear; if the former, it is probably due to a virus, but if it is a neoplastic disease, the morbid or reaction-producing "agent" must still be regarded as the neoplastic process ("urge") itself. The cells of neoplasms more or less continue to exercise the functions of the normal cells from which they originated. One of the normal functions of the endothelial cells in question is, probably, to produce or accumulate lymphocytes near them, and, in fact, the reticulo-endothelial elements together with the lymphoblastic elements constitute "lymphadenoid tissue." In some lesions the crowded lymphocytes tend to dominate the histological picture and make it resemble a lymphosarcoma, whereas in other lesions the Sternberg-Read-Andrewes histological cellular features are more characteristic. In the present case the mainly lymphocytic picture was associated with much fibrosis, just as the Sternberg-Read-Andrewes features generally are (as exemplified in the first case).

(Continued at foot of next column.)

AN INQUIRY INTO REFERRED PAIN.*

By H. H. Woollard, M.D., D.Sc. Melb.,

PROFESSOR OF ANATOMY IN THE UNIVERSITY OF LONDON AT ST. BARTHOLOMEW'S HOSPITAL:

J. E. H. Roberts, O.B.E., M.B. Lond., F.R.C.S.,

SURGEON WITH CHARGE OF OUT-PATIENTS, ST. BARTHOLOMEW'S HOSPITAL;

AND

E. Arnold Carmichael, M.B., F.R.C.P. Edin., M.R.C.P. Lond.,

ASSISTANT TO MEDICAL PROFESSORIAL UNIT, ST. BARTHOLOMEW'S HOSPITAL; AND ASSISTANT PHYSICIAN TO OUT-PATIENTS, NATIONAL HOSPITAL, QUEEN-SQUARE, LONDON.

Recently the hypothesis of Ross, Mackenzie, and Head regarding referred pain has been challenged by Morley[1] as the result of a series of prolonged and careful investigations. These investigations have led Morley to believe that pain resulting from visceral disease is referred to a somatic cutaneous area only when the parietal peritoneum is involved; he utilises the phrenic nerve as an example. Thus when the diaphragmatic region of the abdominal cavity is involved in a disease process, pain is referred to the region of skin supplied by the fourth cervical segment, mostly in the region of the outer end of the clavicle. It had recently been stated by Lemaire,[2] Weiss,[3] and others, that referred pain can be abolished by local anæsthetisation of the cutaneous area to which the pain is referred. If this be so, the theory of referred pain, which is generally accepted, is rendered still more insecure. In support of this, Morley publishes evidence that the referred pain in the shoulder from the diaphragm can be abolished by novocain injection of the shoulder area.

This aspect of the problem of referred pain appeared to us to be worthy of investigation, and we have made observations during the operation of phrenic avulsion under local anæsthesia. The operative procedure was to infiltrate with novocain and adrenalin a line across the neck about two fingers' breadth above the clavicle, so situated that it crossed the posterior border of the sternomastoid muscle.

Through an incision along this line the phrenic nerve was exposed and avulsed.

In all we have been present at nine such operations, and have made the following observations.

Firstly, the area of skin supplied by the third, fourth, and fifth cervical segments was investigated by pin-prick and by means of a soft camel-hair brush to ascertain that sensation was normal. The line of incision was then infiltrated and sensation again tested; it was thus established as to whether the anæsthesia was limited to the line of infiltration or included the supraclavicular nerves. The phrenic nerve was next exposed. By lightly pinching the exposed nerve pain was elicited, and the painful area mapped out. This area was then infiltrated subepidermally in some cases, subcutaneously in others, and both in still others. The nerve was again lightly pinched, and the painful area again mapped out. The nerve was then divided and both ends stimulated. In one or two cases the nerve was injected, then lightly pinched proximally and distally to the injection. Finally the nerve was avulsed.

The following experiment is illustrative of our findings in all.

G.i. (1) Preliminary tests showed that the skin over the right shoulder and cervical region was of normal sensitivity.
(2) Subcutaneous infiltration with novocain and adrenalin along the line of the intended incision caused only anæsthesia limited to the line of the incision.
(3) The phrenic nerve was exposed.
(4) It was lightly pinched, causing the patient to flinch and to complain of severe pain which was localised to an area of about the size of a shilling internal to the acromioclavicular joint.
(5) This area of referred pain was infiltrated in the subepidermal tissues with novocain and adrenalin; and this area on testing was found to be completely anæsthetic.
(6) The phrenic nerve was again lightly pinched; the patient flinched as before and referred the pain to a region slightly below and external to the previous point. The amount of displacement was not more than 1·0–1·5 cm.
Both areas corresponded to areas of reference as mapped out by Head.
(7) This area was further infiltrated and on testing proved to be anæsthetic. Pinching the phrenic consequent to this last infiltration again elicited pain which was on this occasion referred to the previous area of reference, though it was still an anæsthetic area.

Mr. Roberts has repeated these observations in many other cases and has constantly found the same phenomena.

In all nine cases similar results were obtained; in no case was the referred pain altered in character or intensity; in only two was a very small degree of shift determined, and such shift was easily explicable on the difficulty of localising accurately such pain. Stimulation of the distal end of the cut nerve caused no pain, while a stimulation of the proximal end invariably caused referred pain. Thus reference is only obtainable from the proximal end of the divided or blocked nerve. This latter point is of importance in excluding the possibility of the pain having been elicited by stimulation of the tissues around the phrenic nerve. Finally, all the cases on X ray examination following the operation exhibited paralysis of the diaphragm.

CONCLUSIONS.

(1) The diaphragm behaves as a viscus, since light compression of the phrenic nerve occasions no sensation referable to its anatomical site.

(2) On stimulation of the phrenic nerve ascending impulses occur which are felt as pain and are referred.

(3) The area of referred pain is almost identical in all subjects and belongs to the fourth cervical segmental distribution.

(4) Anæsthesia of the area of referred pain in no way affects the character or intensity of the referred pain, and that the locality of the referred pain, apart from the occasional slight shift already mentioned, is not altered. Thus the pain must be due to a reference by higher centres of activity arising in the spinal segment corresponding to the nerve stimulated.

One of us (E. A. C.) carried out this work while in receipt of a *personal grant from the Medical Research* Council.

THE LEUCOPOIETIC VALUE OF SULPHUR.

By T. D. Power, M.D. Dub., M.R.C.P. Lond.,
D.P.H., D.P.M.,
DEPUTY MEDICAL SUPERINTENDENT, BRENTWOOD MENTAL HOSPITAL.

For the past two years injections of sulphur in oil have been widely employed in the treatment of a variety of conditions, prominent among which are general paralysis of the insane and dementia præcox. The primary object of the therapy is to produce a series of pyrexial bouts, and any good results which ensue are usually attributed to the beneficial effects of the fever. On a previous occasion,[1] I drew attention to the fact that intramuscular injections of sulfosin * are almost invariably followed by a considerable degree of leucocytosis, which may persist for as long as 48 hours, and which tends to increase rather than to diminish as the treatment progresses. Since that time, it has been possible to carry out a number of animal experiments, the results of which may be of some interest to those who employ this drug in clinical practice.

EXPERIMENTS ON ANIMALS.

If a rabbit is given a series of daily injections of sulfosin, an increase in the number of white cells in circulation becomes evident within a few days, and this leucocytosis is more or less maintained as long as the treatment is continued. Fig. 1 illustrates very well what occurs. On it are recorded the results of a number of leucocyte counts, performed daily on a rabbit, over a period of nine weeks.

For the first four weeks, during which no sulphur was administered, control observations were made, and the broken line indicates that throughout this period the number of leucocytes never exceeded 9000 per c.mm. The temperature (unbroken *line*) varied between 101·2° and 103·4° F. which is within the limits of normality for a rabbit. A the commencement of the fifth week the animal was given an injection of 1 c.cm. of sulfosin, and this dose was repeated on 23 consecutive days. After the fourth of these injection the leucocytic curve commenced to rise, and remained above the normal upper limit during the whole period o inoculation. Well-marked oscillations occurred from tim to time, and the highest count recorded was 25,500 per c.mm When 23 doses had been administered the sulfosin wa discontinued, and thereafter the number of leucocytes began to diminish, normal limits being regained within a few days

The leucocytosis was due to an increase of polymorphonuclear cells, which corresponds with wha occurs under similar circumstances in man. Th animal appeared to suffer no discomfort throughou the experimental period, except on one occasion after the twenty-third injection, when it seemed ou of sorts, and exhibited a subnormal temperature A day or two after the withdrawal of the dru, this indisposition had completely passed away, and the rabbit seemed as lively and healthy as ever It will be noticed that no marked elevations o temperature appear upon the chart, but this is probably because readings were taken only once in the 24 hours.

---

[1] Power, T. D.: THE LANCET, 1930, ii., 1289.

* This is the trade name given to a preparation consisting of 1 per cent. suspension of sulphur in oil.

The above experiment was repeated on eight rabbits with substantially the same results. The bone-marrows of these animals were submitted to microscopical examination, and in every case a marked degree of hyperplasia was found to have occurred. This varied in proportion to the amount of sulfosin administered, and in some cases was evident macroscopically as well as microscopically. The leucoblastic tissue was most affected, but the erythroblastic elements and megakaryocytes did not entirely escape. Fig. 2 illustrates the general appearance of such a bone-marrow, and may be compared with Fig. 3, which represents the same organ of an untreated rabbit under identical magnification. Both specimens were taken from the femur. It will be noticed that in the case of the treated

FIG. 1.

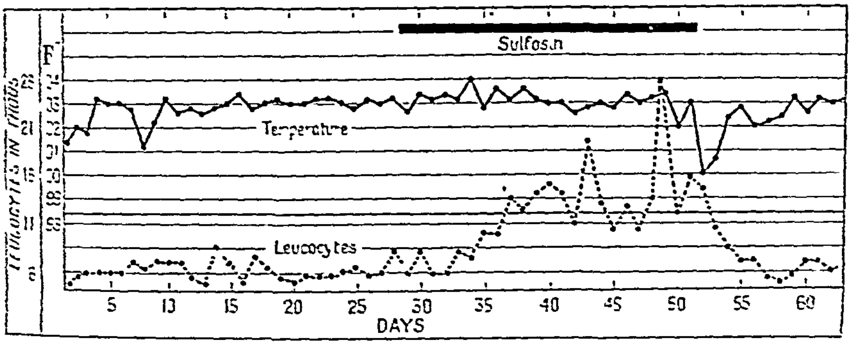

Chart showing effect of sulfosin on temperature and leucocyte count (in thousands)

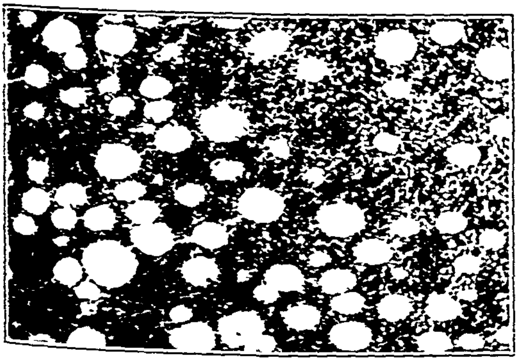
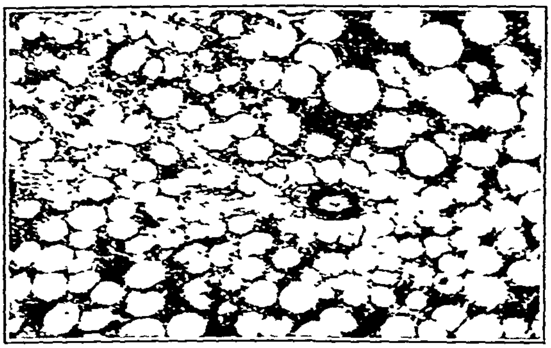
FIG. 2.



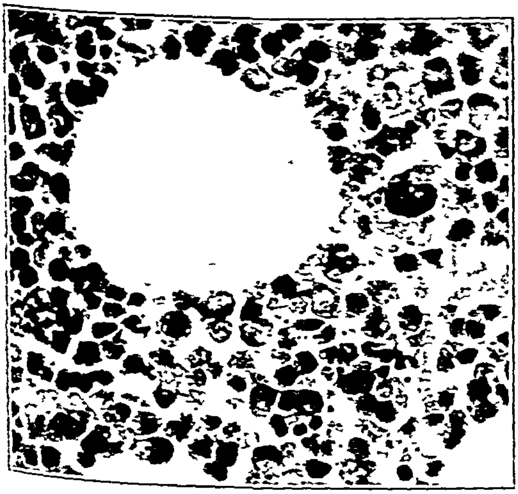
Illustrates hyperplastic condition of bone-marrow after administration of 29 injections of sulfosin. Note the decrease in number of fat spaces, and marked excess of cellular tissue. (× 75.)

FIG. 3.



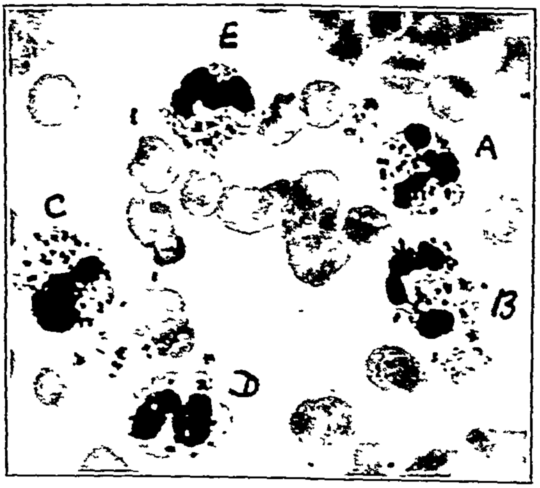
Illustrates appearance of normal rabbit's bone-marrow taken at same magnification as Fig. 2. (× 75.)

FIG. 4.



A higher magnification of hyperplastic bone-marrow shown in Fig. 2. Illustrates in detail nature of newly formed cellular elements. The cells with deeply staining nuclei are erythroblasts, while those with granular cytoplasm are either myelocytes or polymorphonuclear leucocytes. There are two giant cells in the photograph. (× 560.)

FIG. 5.



Phagocytosis following sulfosin administration. Blood taken from patient exhibiting leucocytosis and incubated with bacteria. Cells marked A, B, and C are mature polymorphonuclear leucocytes, and have ingested a considerable number of cocci: cells E and D have not yet begun to show nuclear lobulation, and only manifest slight phagocytic activity. (× 1000.)

Through an incision along this line the phrenic nerve was exposed and avulsed.

In all we have been present at nine such operations, and have made the following observations.

Firstly, the area of skin supplied by the third, fourth, and fifth cervical segments was investigated by pin-prick and by means of a soft camel-hair brush to ascertain that sensation was normal. The line of incision was then infiltrated and sensation again tested; it was thus established as to whether the anæsthesia was limited to the line of infiltration or included the supraclavicular nerves. The phrenic nerve was next exposed. By lightly pinching the exposed nerve pain was elicited, and the painful area mapped out. This area was then infiltrated subepidermally in some cases, subcutaneously in others, and both in still others. The nerve was again lightly pinched, and the painful area again mapped out. The nerve was then divided and both ends stimulated. In one or two cases the nerve was injected, then lightly pinched proximally and distally to the injection. Finally the nerve was avulsed.

The following experiment is illustrative of our findings in all.

G.i. (1) Preliminary tests showed that the skin over the right shoulder and cervical region was of normal sensitivity.

(2) Subcutaneous infiltration with novocain and adrenalin along the line of the intended incision caused only anæsthesia limited to the line of the incision.

(3) The phrenic nerve was exposed.

(4) It was lightly pinched, causing the patient to flinch and to complain of severe pain which was localised to an area of about the size of a shilling internal to the acromio-clavicular joint.

(5) This area of referred pain was infiltrated in the subepidermal tissues with novocain and adrenalin; and this area on testing was found to be completely anæsthetic.

(6) The phrenic nerve was again lightly pinched; the patient flinched as before and referred the pain to a region slightly below and external to the previous point. The amount of displacement was not more than 1·0–1·5 cm. Both areas corresponded to areas of reference as mapped out by Head.

(7) This area was further infiltrated and on testing proved to be anæsthetic. Pinching the phrenic consequent to this last infiltration again elicited pain which was on this occasion referred to the previous area of reference, though it was still an anæsthetic area.

Mr. Roberts has repeated these observations in many other cases and has constantly found the same phenomena.

In all nine cases similar results were obtained; in no case was the referred pain altered in character or intensity; in only two was a very small degree of shift determined, and such shift was easily explicable on the difficulty of localising accurately such pain. Stimulation of the distal end of the cut nerve caused no pain, while a stimulation of the proximal end invariably caused referred pain. Thus reference is only obtainable from the proximal end of the divided or blocked nerve. This latter point is of importance in excluding the possibility of the pain having been elicited by stimulation of the tissues around the phrenic nerve. Finally, all the cases on X ray examination following the operation exhibited paralysis of the diaphragm.

CONCLUSIONS.

(1) The diaphragm behaves as a viscus, since light compression of the phrenic nerve occasions no sensation referable to its anatomical site.

(2) On stimulation of the phrenic nerve ascending impulses occur which are felt as pain and are referred.

(3) The area of referred pain is almost identical in all subjects and belongs to the fourth cervical segmental distribution.

(4) Anæsthesia of the area of referred pain in no way affects the character or intensity of the referred pain, and that the locality of the referred pain, apart from the occasional slight shift already mentioned, is not altered. Thus the pain must be due to a reference by higher centres of activity arising in the spinal segment corresponding to the nerve stimulated.

One of us (E. A. C.) carried out this work while in receipt of a personal grant from the Medical Research Council.

THE LEUCOPOIETIC VALUE OF SULPHUR.

By T. D. Power, M.D. Dub., M.R.C.P. Lond., D.P.H., D.P.M.,

DEPUTY MEDICAL SUPERINTENDENT, BRENTWOOD MENTAL HOSPITAL.

For the past two years injections of sulphur i oil have been widely employed in the treatment a variety of conditions, prominent among whic are general paralysis of the insane and dementi præcox. The primary object of the therapy is t produce a series of pyrexial bouts, and any goo results which ensue are usually attributed to the beneficial effects of the fever. On a previous occasion,[1] I drew attention to the fact that intramuscular injections of sulfosin * are almost invariably followed by a considerable degree of leucocytosis, which may persist for as long as 48 hours, and which tends to increase rather than to diminish as the treatment progresses. Since that time, it has been possible to carry out a number of animal experiments, the results of which may be of some interest to those who employ this drug in clinical practice.

EXPERIMENTS ON ANIMALS.

If a rabbit is given a series of daily injections of sulfosin, an increase in the number of white cells in circulation becomes evident within a few days, and this leucocytosis is more or less maintained as long as the treatment is continued. Fig. 1 illustrates very well what occurs. On it are recorded the results of a number of leucocyte counts, performed daily on a rabbit, over a period of nine weeks.

For the first four weeks, during which no sulphur was administered, control observations were made, and the broken line indicates that throughout this period the number of leucocytes never exceeded 9000 per c.mm. The temperature (unbroken line) varied between 101·2° and 103·4° F., which is within the limits of normality for a rabbit. At the commencement of the fifth week the animal was given an injection of 1 c.cm. of sulfosin, and this dose was repeated on 23 consecutive days. After the fourth of these injections the leucocytic curve commenced to rise, and remained above the normal upper limit during the whole period of inoculation. Well-marked oscillations occurred from time to time, and the highest count recorded was 25,500 per c.mm. When 23 doses had been administered the sulfosin was discontinued, and thereafter the number of leucocytes began to diminish, normal limits being regained within a few days.

The leucocytosis was due to an increase of polymorphonuclear cells, which corresponds with what occurs under similar circumstances in man. The animal appeared to suffer no discomfort throughout the experimental period, except on one occasion, after the twenty-third injection, when it seemed out of sorts, and exhibited a subnormal temperature. A day or two after the withdrawal of the drug this indisposition had completely passed away, and the rabbit seemed as lively and healthy as ever. It will be noticed that no marked elevations of

---

[1] Power, T. D.: The Lancet, 1930, ii., 1289.

* This is the trade name given to a preparation consisting of a 1 per cent. suspension of sulphur in oil.

In the case of extreme catatonic stupor the difference in the temperature response to sulfosin was so marked that it is considered separately from the other 22 cases. The maximum temperature obtained was 101·8° F. and the smallest peak was 99·0° F. The mean of all the peaks was 100·4° F. The technique of the injections was in all respects similar to that employed in the other cases, and the patient has not improved in the 14 months which have ensued since the injections.

Only definite cases of dementia præcox were included and, of course, no case displaying any physical abnormality was subjected to the treatment. There was no discrimination on the question of the probable duration, the longest being of at least 11 years' standing and the most recent being of at least two to three years' duration. Cases in which a definite degree of mental deterioration was obvious were not included in the series. In no case can it be claimed that complete normality ensued, but seven cases showed varying degrees of improvement, and the remaining 16 cases showed no improvement at all. Of the cases which showed improvement, four showed a marked improvement, and three a moderate improvement. Even in the cases that improved most markedly the shadowy background of the psychosis, best described as a definite "schizophrenic personality," persisted. Six months has elapsed since the last of the series was treated, and one case has relapsed—i.e., one of the four showing marked improvement.

The above results are not very encouraging, and this all the more so when one takes into account how difficult it is to assess how far any improvement can be attributed to sulfosin, since the possibility of the occurrence of spontaneous improvement has to be considered. Assuming that the sulfosin is responsible for certain of the improvements recorded, it has yet to be determined whether these beneficial results are due to the pharmacological effects of the sulfosin or to a possible factor suggested by McCowan—i.e., the intensive individual nursing attention that patients undergoing the treatment receive. However, a therapeutic measure which may hold out any hope of even a slight improvement in the prognosis of this disease appears to be justified until supplanted by something more specific.

I am indebted to Dr. F. L. Golla, Dr. P. K. McCowan, and Dr. N. Roberts for their interest, and to the latter for permission to publish the cases.

CLINICAL AND LABORATORY NOTES

VARIOLA MINOR COMPLICATED BY APPENDICITIS DUE TO THREADWORMS.

By A. T. W. POWELL, M.C., M.B., B.S. LOND., D.P.H.,

MEDICAL OFFICER OF HEALTH FOR THE BOROUGH OF WALTHAMSTOW.

A BOY, aged 13, unvaccinated, was notified by Dr. William Menzies on Jan. 19th, 1931, as suffering from variola minor. He was removed to Walthamstow Small-pox Hospital on the same day for isolation and treatment.

The onset of illness with backache and headache was on Jan. 14th, and the rash appeared on the 18th. On admission to hospital on the 19th, there was a copious eruption, but the boy had little or no constitutional disturbance and no fever. On the 29th, however, a fresh eruption occurred which was entirely superficial and of an urticarial character. On this day the hospital was visited by Dr. W. V. Shaw who saw this patient. He remarked that a secondary eruption sometimes occurred during the period of desquamation in small-pox. In view, however, of later findings in this case the urticaria may have been due to another cause. The secondary eruption increased in extent until Jan. 31st, when it began to subside.

A few days later, on Feb. 3rd, this boy suffered some pain in the abdomen and by the next day had slight pyrexia and a pulse-rate of 92 per minute. On examination it was found that there were few physical signs, but some tenderness on deep pressure in the right iliac fossa was discovered; also rectal examination caused pain in the right side of the abdomen. A provisional diagnosis of appendicitis was made and the patient was kept under close observation. Four-hourly temperatures were taken and by 10 P.M. it was found that the temperature was 102° F. and the pulse-rate 110 per minute. By this time a diagnosis of appendicitis seemed quite clear.

The boy had recovered from his attack of variola minor, desquamation was complete, and in fact, he might have been discharged, but probably *no general hospital would have* accepted him as a patient.

Mr. M. J. Smyth, saw the patient in the early hours of Feb. 5th, and confirmed the diagnosis of appendicitis. He had brought the necessary instruments and dressings and a two-bed hut was hastily improvised as an operating theatre.

The operation was straightforward and no complications were met with. A long appendix with no external inflammation and apparently normal was removed. Subsequently, when the appendix was opened a small area of inflammation was found about the middle of its length, and half a centimetre in diameter. In the centre of this inflamed area was a single threadworm.

The patient made an uneventful recovery and was discharged on Feb. 23rd.

A CASE OF ANTHRAX.

By G. DE BEC TURTLE, M.D. DURH., M.R.C.P. LOND.

A WOMAN, aged 71, consulted me complaining of a painful swelling at the back of her neck, which she thought was the result of a sting three days previously. She looked ill and very toxæmic, the temperature was 99° F., and the pulse-rate 100. On examination there was a minute black spot with one vesicle at the side, situated over the seventh cervical spine, a large surrounding area being indurated, and malignant pustule was suspected.

In the evening of the same day the temperature had risen to 102° F., and the pulse to 112. The induration had increased, and the black spot was larger, several vesicles having appeared around it. A microscopical search of the serum from a vesicle did not reveal any anthrax bacilli, and it was concluded that the infection must be streptococcal in origin; 20 c.cm. of anti-scarlet fever serum was injected subcutaneously. On the following morning the temperature was 100° F., and the pulse-rate 100, and the patient's general condition appeared a little better, but the local condition had not altered at all. By the afternoon of the same day, however, the temperature was 102° F., and the pulse-rate 104, and the induration had markedly increased, extending round the neck and down over the clavicles into the breast tissue. Excision of the pustule was decided upon, and the same evening was performed under gas-and-oxygen anæsthesia, a large area being excised. A crucial incision was made, and four flaps dissected animal there is a definite diminution in the number of the fat spaces, and a corresponding increase in the cellular elements, which, of course, consist of developing blood corpuscles. A better idea of the nature of the newly formed tissue may be obtained from Fig. 4, which depicts the same specimen as that shown in Fig. 2 under higher magnification. The majority of the cells appearing in this photograph consist of myelocytes or polymorphonuclear leucocytes, but there is a fair sprinkling of darkly stained erythroblasts, and two megakaryocytes are also seen. The nucleus of one of the latter appears to be pyknotic, but this is not an uncommon finding in the bone-marrows of normal rabbits.

PHAGOCYTIC ACTIVITY.

I have given only the barest outline of these animal experiments, but anyone who is sufficiently interested can repeat them for himself. I cannot conclude, however, without briefly referring to another aspect of sulphur therapy as applied to the human subject. A certain number of patients in whom a leucocytosis has been evoked in this way exhibit a "shift to the left" of the Schilling index, and this "shift" tends to become more marked with a repetition of the injections. It occurred to me that it might be of some interest to investigate the behaviour towards bacteria of such strongly stimulated leucocytes when incubated with the patient's own serum.

With this object in view, I utilised the technique devised by Knott [2] for the purpose of controlling the doses of X rays in the treatment of leukæmia. An emulsion of well-washed staphylococcal bacteria was incubated with four times its volume of a sample of blood obtained from a patient the day after an injection of sulfosin. The individual in question showed at the time a considerable leucocytosis, with a well-marked "shift to the left" of the Schilling index. After the lapse of 20 minutes the mixture was removed from the incubator, and stained preparations made in the ordinary way. Fig. 5 depicts a photomicrograph of one of these blood smears, and shows very clearly what has occurred. The cells marked A, B, and C are mature polymorphonuclear leucocytes, and have ingested a considerable number of bacteria, whereas the cells E and D, where nuclear lobulation is only just about to commence, manifest phagocytic activity to a very poor degree. The experiment was repeated on several occasions with the same result.

The experiments described show that sulfosin is a powerful leucoblastic stimulant, and the leucocytes which appear in the circulation are capable—at any rate in vitro—of exhibiting a degree of phagocytic activity. Whether or not this property of sulphur might be utilised clinically is a very different matter, but at all events it is as well that those who induce fever by this method should be aware of what is taking place in the patient's body.

In conclusion, I may mention that, from the standpoint of research, sulfosin has a very definite value, for when it is employed in conjunction with vital staining, beautiful microscopical preparations illustrating the developmental history of the blood-cells can be obtained.

---

[2] Knott, F. A.: Guy's Hospital Rep., April, 1930.

NORTHAMPTON GENERAL HOSPITAL.—During the year ended July 1st, 1931, the in-patients numbered 4207, a slight increase; 254 were private patients. Their average stay was 19 days, and their average cost £7 19*s*. 3*d*., a reduction of 2*s*. 4*d*. The average daily cost per bed was 8*s*. 8*d*., a reduction of 5*d*. There were 18,230 out-patients, a small increase; the average cost of each was 7*s*. Nearly one-fourth of the in-patients spent an average of 13 additional days in the Margaret Spencer Home of Rest, which is now used as a hospital for recovery for cases needing further treatment. An out-patient clinic for the treatment of early mental cases has been established.

TREATMENT OF DEMENTIA PRÆCOX WITH SULFOSIN.

BY WILLIAM MCCARTAN, M.D., D.P.H. BELF., D.P.M

SENIOR ASSISTANT MEDICAL OFFICER, WEST PARK MENTAL HOSPITAL, EPSOM.

A SERIES of 23 cases of dementia præcox has be treated with sulfosin, introduced and advocat by Schroeder.

The injections were made into the tissues imm diately around the periosteum of the femur, t needle being passed into the middle third of t lateral aspect of the thigh. The danger of femo periostitis appeared to be very real and consequen aseptic precautions were rigid. A more rem danger is that of oil embolism and a routine pract was made of attempting to withdraw the plun of the syringe a little when the latter was in situ a of refraining from introducing sulfosin into the th if the least quantity of blood in the syringe show that a vessel of any size had been inadverten punctured. Blood was withdrawn on three differ occasions during the series.

The usual procedure was *to start with* doses 1 c.cm. and repeat the dose at four-day interv increasing by 1 c.cm. at each subsequent inject until a total of eight to ten injections had been giv Rapid general debilitation was noticed in most ca but this was transient and at the end of a course injections patients rapidly regained their nor state of nutrition. Apart from this temporary of weight and a certain stiffness and discomfor the legs at the site of the injections, no phys disability could be attributed to the sulphur. case certainly did appear to develop a pye subsequently, but in this case it is believed that condition had been somewhat remotely pre-exist and had been latent during the treatment.

The pyrogenetic action of sulfosin was mar in all patients except one—a case of extreme catat stupor which will be referred to separately la The temperature commenced to rise usually in f seven to ten hours from the time of the inject but periods of as short as three hours and as lon 20 hours were noted. In each patient the lengt this "incubation period" varied greatly with different injections. This variation was enti irregular and corresponded in no way with the of the injection. Similar irregularity was obse in the time it took the temperature to reach maximum—e.g., in one case it took only one to reach a maximum of 104° F. after the fo injection but after the fifth injection it took 20 h to reach a maximum of 103·8° F. The duratio the fever on each occasion was usually somew between 30 and 40 hours, but here again there a wide irregularity, the shortest pyrexial period b ten hours (maximum temperature on this occa being 102·8° F.), the longest pyrexial period b 62 hours (the maximum temperature on this occa being 102·4° F.). The case which subseque showed a flare-up of a pre-existing pyelitis did pre on one occasion a temperature which lasted 72 ho but one is inclined to assume that the pyrexia in case may have been influenced by the latent condi of the kidneys. The mean of the height of all peaks of all cases (excluding the one case of catat stupor already referred to) was 103·2° F. The smal peak recorded in any case was 100·2° F., the high 104·6° F.

MEDICAL SOCIETIES

MANCHESTER MEDICAL SOCIETY.

A MEETING of this society on Feb. 3rd, with Prof. J. S. B. STOPFORD, the President, in the chair, was devoted to

Poliomyelitis.

Dr. R. W. FAIRBROTHER said that there seemed to be no doubt that the causative agent was a small particulate body belonging to the group of filtrable viruses. As it could not be cultivated by the ordinary means it could only be studied by animal inoculation. The following properties had been established, despite experimental difficulties; it was extremely resistant to freezing, drying, pure glycerin, and 0·5 per cent. phenol, but was readily destroyed by heat over 45° C. and oxidising agents. It retained its activity when left in milk at room temperature for 30 days. It could not yet be obtained entirely free from nervous tissue, which might modify its activity.

The epidemiology of the disease presented a fascinating but complex problem, and the theory propounded to explain it was that the virus was usually present in a populous community and infected a large number of people, most of whom developed a "sub-clinical" infection and so acquired immunity and became healthy carriers. Those who had actually developed the disease were usually children between the ages of 1 and 12; infants probably escaped owing to limited exposure to infection and the presence of maternal antibodies in their blood. Most children over 12 had acquired immunity, and after a widespread outbreak the majority of people had marked immunity, so that the soil was not suitable for the persistence of the virus. The chance of sub-clinical infections occurring during the next few years was then diminished, and a susceptible community might be produced. The introduction of the virus into a virgin population had caused extensive outbreaks involving persons of all ages.

The mode of spread was probably droplet infection from the nasopharynx. but some authorities held that drinking water or milk might convey the disease. The seasonal incidence remained unexplained. There was a difference in individual response, producing spinal, bulbar, and abortive forms of the disease, as well as certain rare and ill-defined varieties. The variations depended on the dosage of the virus received and possibly on different strains, as well as on the degree of resistance of the individual. Recent researches suggested that the virus, invading the tissues of the nasopharynx, passed to the brain by the axons of the olfactory nerve and thence to the cord by the motor fibres of the pyramidal tract, attacking various nerve-cells on the way. There was no evidence to suggest that it travelled via the cerebro-spinal fluid or the blood stream.

The clinical picture was very varied; there was frequently a prodromal stage characterised by fever, headache, vomiting, and malaise, with typical changes in the cerebro-spinal fluid—a pleocytosis, first polymorphonuclear and then mononuclear, and slight increase in the globulin, with no alteration in the sugar and chloride content. The mortality varied, but was usually about 10 per cent., and death was often due to involvement of the respiratory and cardiac centres. The characteristic lesions found post mortem were degeneration and vacuolation of the nerve-cells with neuronophagia, perivascular and meningeal infiltration.

Active measures should be commenced in the prodromal stage, and it seemed advisable, when poliomyelitis was in the locality, to regard all vague pyrexial conditions as potential cases and to examine the cerebro-spinal fluid. General measures included immediate isolation, rest, fluid diet, attention to the bowels, and symptomatic treatment. With these *measures alone many cases cleared up entirely.*

SPECIFIC THERAPY.

Protective immunisation could not be produced actively; the danger of introducing active virus into human beings was too great at present. Much progress in passive immunisation had been made during the last two years. It was essential that any serum used should possess a definite marked antiviral activity, and this could only be tested by the neutralisation test on monkeys. Convalescent human serum had proved extremely valuable, but its disadvantage lay in the time and trouble required to collect large quantities, and the need for preliminary precautionary tests on volunteers. Normal human serum might prove useful when antiviral serum was not obtainable, but strict neutralisation tests were necessary, since not every human serum was satisfactory. Immune monkey serum had very limited value, for the yield of serum per monkey was very small. Immune horse serum had only been fully investigated recently; only a limited number of horses produced a satisfactory serum, but those that did produced a good deal of it. There appeared no scientific justification for the use of antistreptococcal serum.

The serum used should be filtered, subjected to full sterility tests, sealed in ampoules, and stored at a low temperature. There seemed to be no reason why all large hospitals for children should not keep a stock of it. In the event of an outbreak of poliomyelitis all contacts, especially children, should receive a prophylactic dose of about 20–25 c.cm. intramuscularly. If the outbreak did not subside a further dose should be given after four or five weeks. Desensitisation would then be necessary. Similar treatment might be employed for doubtful cases before diagnosis was made, and gargling with antiseptic lotions might also be useful.

Therapeutically, the earlier the serum was given the better. It was therefore a good plan to examine the cerebro-spinal fluid at the bedside so that the serum could at once be given intrathecally if the diagnosis was confirmed. As large a dose as possible should be given; an average was 20 c.cm. intrathecally, warmed to 37° C., and 30 c.cm. intramuscularly or intravenously. The dose should be repeated every 24 hours until improvement was observed. The patient must be kept under observation for some time after the attack had settled down, as delayed attacks sometimes occurred. The results of serum treatment were not so successful after paralysis had appeared, but it might limit the spread of the lesions and so reduce the amount of permanent damage; it should therefore always be given. There seemed no doubt whatever of the beneficial effects of therapeutic serum. Its administration was comparatively harmless, whereas failure to give it might cause lifelong crippling.

back, exposing an area about 2 inches in diameter. The most severely indurated tissue was excised and the wound was packed. As will be seen from the pathologist's notes, anthrax bacilli were grown in scanty numbers from a portion of the excised material.

Sclavo's serum (40 c.cm.) was administered immediately after the report from the pathologist was received, and 10 c.cm. more the next day. The temperature fell, the pulse improved, and the indurated area began to decrease in size. The wound was dressed at first with solution of perchloride of mercury 1 in 2000, later with acriflavine, and finally with eusol. The patient has made a slow but uneventful recovery.

Pathologist's report.—Swabs taken showed in direct smears one or two isolated cocci and an occasional pair of degenerate cocci. There were no cells present in the exudate. Cultures gave a very scanty growth of *Staphylococcus albus*. Cultures from the excised material on the following day showed two colonies of staphylococci and two colonies of *B. anthracis* on six heavily inoculated tubes. The organisms were therefore extremely scanty, and none was detected in direct smears. The identity of the colonies of *B. anthracis* has been established by inoculation into mice; the mice died between 24 and 32 hours after inoculation with a pure culture of the bacilli, and post-mortem bacillus anthrax in very large numbers and pure culture was recovered from heart's spleen pulp and peritoneal exudate. The swabs from the wound taken four days later showed pus cells and large numbers of staphylococci, and the cultures have given a pure growth of *Staphylococcus aureus*.

The case is of interest as occurring in a patient who lived in a hotel, a community where anthrax is not likely to be met with or suspected. No history could be obtained of any recent purchase of furs or new brushes, in fact it was entirely negative.

I am greatly indebted to Mr. Arthur Edmunds and Dr. E. ff. Creed for their assistance.

London, W.

A CASE OF
PSYCHOSIS WITH HYPERTHYROIDISM
TREATED BY ERGOTAMINE.

By John H. Ewen, M.R.C.S. Eng., D.P.M.,
ASSISTANT MEDICAL OFFICER, SURREY COUNTY MENTAL HOSPITAL, NETHERNE.

Among others, Rothlin[1] and Porges and Adlersberg[2] have studied the action of ergotamine in endocrine disorders, especially Graves's disease. Ergotamine is an inhibitor of the sympathetic, its action being analogous to that of atropine on the parasympathetic. It diminishes the tonus of the sympathetic, and according to Maier[3] this beneficial diminution persists after discontinuing the treatment. Its use in Graves's disease is not without danger, and Labbé and Besançon[4] have recorded cases in which its exhibition has been followed by hemiplegia and collapse; but, as Porges has pointed out, there is often a personal idiosyncrasy to ergotamine in cases of hyperthyroidism, and these ill-effects may be avoided by adopting a judicious dosage and regulating the dose to the individual case.

The undoubted benefit conferred by ergotamine in certain cases of hyperthyroidism seems to justify its employment in the mental disorders associated with exophthalmic goitre, and in the case described below its use was followed by most encouraging results.

A married woman, aged 30, was admitted under certificate to Netherne Mental Hospital on Jan. 21st, 1931. For some time previously she had been receiving treatment at a private mental hospital.

Mental state.—She was excited, restless, confused, and extremely impulsive. Her conversation was disconnected, rambling, and almost incoherent, and she displayed complete lack of insight. She had vague persecutory ideas, and was suspicious and apprehensive. At times she became very agitated, and laughed and cried without reason. She was particularly prone to emotional outbursts, during which time she showed several marked mannerisms. On the day after admission she made a determined attempt to escape, and on several occasions only the most careful supervision circumvented her efforts to get away. A month afte admission she made a serious attempt at suicide, and following this she was regarded as actively suicidal an placed under special care. Briefly, she was entirely irresponsible, and her mental condition was such that a mos guarded prognosis was indicated.

Physical condition.—She was sallow and thin. Pulse rate 70, regular. There was some slight enlargement o the thyroid and exophthalmos was present but not marked There was no tremor. A month after admission, howeve the signs of exophthalmic goitre became more eviden There was tachycardia, with tremors of the hands, and th exophthalmos became obvious. The thyroid increased i size, and the circumference of the neck appeared to var with her mental state, being greater when her ment symptoms were worse. At this period the basal metaboli rate was +32·9 (Read's formula).

Treatment.—Five months after admission treatment b ergotamine was commenced. Subcutaneous injections 0·25 c.cm. ergotamine tartrate were given daily and, i the absence of secondary effects, the dose was increased 0·5 c.cm. This was continued for three weeks, and followe by oral administration of 0·001 g. ergotamine t.d.s. for anoth three weeks. At the same time dietetic measures we adopted, and proteins reduced to a minimum. Milk a butter were also restricted, and carbohydrates increase Under this régime she lost 4 lb.

Results of treatment.—Mentally there has been very evide improvement. The patient is now rational, convers normally, and displays marked insight. The agitation h completely disappeared, and the restlessness and impulsiv ness which were such a feature of her previous mental sta have been replaced by calmness and judgment. There is realisation of responsibility, and in place of confusion logical sequence of thought. Her mannerisms have d appeared. With regard to the thyroid condition, there now very little enlargement of the gland. Tremor a tachycardia are absent, and exophthalmos is only very sligh The basal metabolic rate is +27·5 (Read's formula). S has been discharged, and the latest reports indicate th she is leading a normal useful life.

This case is remarkable for the severity of t mental symptoms, the difficulty of prognosis, a the rapidity of improvement under ergotamine.

I am indebted to Dr. P. C. Coombes, medic superintendent of Netherne Mental Hospital, f permission to publish these notes.

[4] Quoted by Porges (ref. 2).

Prince of Wales's Hospital.—Sir Albert Barra recently laid the foundation-stone of a new out-patien department at this Tottenham hospital which, when co pleted, will cost £30,000, and will include tonsil and aden departments and wards for paying patients. Owing lack of means, the first part only of the scheme is bei undertaken at present.

From "Cottage" to "General" Hospital. During the past fortnight the governing bodies of t cottage hospitals, Romford and Malmesbury, have decid to call them general hospitals. The reason given for t change at Victoria Cottage Hospital, Romford (33 bed is that the limitation in the name makes it difficult obtain nurses, and that probationers feel that they wasting their time at "a dead end with no prospects." 1931, the number of in-patients was 598, a reduction of owing to the hospital having been partially closed for rep and decoration. The Malmesbury Cottage Hospital a Maternity Home (30 beds) is to omit the word "cottag because, "in view of the status the hospital has acquir the committee consider that the prefix is rather a misnome There were 370 in-patients last year, the largest numb yet admitted.

pulmonary suppuration was not always acute in onset, nor always markedly febrile. In chronic abscess, especially after rupture, the fever was often irregular; a copious discharge of pus was often succeeded by an apyrexial stage. This usually indicated an abscess opened into a bronchus but not draining effectively, with periodic retention and partial evacuation. An early symptom often noted by the patient was an unpleasant taste or a sensation of foul gas about the breath; this sometimes preceded actual rupture by several days. In gangrene the discharge was extremely foul, and masses of necrotic lung tissue might be found in it. Hæmoptysis occurred in about 70 per cent. of the cases and, especially in gangrene, might be so profuse as to be fatal. Pain was usual, and sometimes was severe; in chronic cases the dyspnœa might be slight. Sometimes lung abscess developed without either rigors or profuse sweats. Often the physical signs were slight and equivocal; before a superficial abscess ruptured there might be dullness with weak breath sounds and perhaps a few râles because of congested lung tissue around. In chronic abscess clubbing of fingers might develop in as short a time as eight weeks.

Radiological evidence was very valuable; it was sometimes conclusive, and it helped to localise the abscess. When surgery was likely to be invoked radiograms taken in different positions were indispensable. After rupture the appearance of a fluid level in the cavity was diagnostically helpful; hence a radiogram with the patient erect should always be taken. Lipiodol he found useful in excluding other conditions; usually lipiodol did not enter the abscess cavity, for the entering bronchus was, in most cases, obstructed. Almost invariably the blood of these patients showed leucocytosis up to 20,000 or 30,000, with a relative polymorphonuclear increase. When rupture took place the discharge was almost pure pus; elastic tissue was almost always present. Exploratory puncture being dangerous, should not be employed, for it might lead to a widespread infection of the pleura and of the needle-tract, or might precipitate rupture into a bronchus.

Treatment should be medical in acute cases, at least until the suppurative process was localised. With medical attention a proportion of patients—variously stated at from 10 to 30 per cent.—recovered completely after rupture. When rupture occurred, the patient should be turned to the affected side; otherwise, with large abscesses, there was risk of suffocation. Postural drainage was of great value, and if the patient's condition permitted, he should hang over the bed at least twice daily to encourage evacuation by coughing. When cases were almost afebrile a creosote vapour-bath could be given. Organic arsenical compounds could be given in gangrenous cases and those with fœtid sputum.

Dr. Young concluded by stating his views on the surgical aspect. He remarked that he considered artificial pneumothorax dangerous and undesirable; frequently, however, phrenic avulsion was of value. Lobectomy might be a method of choice.

SURGICAL TREATMENT.

Mr. J. B. HUNTER dealt only with single abscess, and only such as occurred without dilatation of bronchi. Lung abscess was more common, in his view, than was generally recognised. There was a form of small abscess, usually in the upper lobe, which was completely evacuated after violent coughing, and was cured spontaneously without its presence having been suspected. Men had this condition more than women, and it was commoner in the right than in the left lung. The character of the abscess depended much on the patient's resistance, the virulence of the organisms, and the position of the abscess. The closed type of abscess needed surgery much more than did the acute type which was draining into a bronchus. The onset was usually abrupt, and might be heralded by rigors, or by less severe fever and milder malaise. In the acute stage blood was present in the sputum, altered in character, and the sputum was frothy. Radiological appearances were very helpful; a shadow could be seen in the affected lobe, circular in shape, with a fuzzy outline. Usually there was a clear area between it and the mediastinum. In rare cases the fluid level could be seen. Diagnostic needling of the lung should not be carried out, as one could not know whether pleural adhesions were present. A considerable number of patients got well with expectant treatment, mostly those with abscess of the upper lobe, the difficult site to deal with surgically.

Mr. Hunter held that the choice of the anæsthetic was very important; the lung was already damaged, and a large abscess might burst into a bronchus during manipulation and drown the patient. Some non-irritating anæsthetic should be used; his own preference was for gas and oxygen preceded by avertin. When bronchial fistula occurred it was due to inadequate collapse of the chest wall at the time of operation. Two further possible complications, even in the absence of any operation, were secondary bronchiectasis and abscess of the brain. His view was that many lung abscesses were due to a combination of embolism and the use of a volatile anæsthetic.

Dr. JAMES MAXWELL said that gangrene of the lung was the result, mainly, of a necrotic process, due to interference of the blood-supply. Lung abscess was a not uncommon sequel of lobar or bronchopneumonia, and the aspiration of septic material was probably the second most frequent cause. If adequate drainage could be established, the tendency was always towards healing; hence, at first, the treatment should be expectant. Often bronchoscopic drainage was useful. As a rule, artificial pneumothorax should not be attempted, and surgery should be reserved for cases which had become chronic; certainly it should be employed if no improvement was manifest at the end of ten weeks.

RADIOGRAPHY AND BRONCHOSCOPY.

Dr. PETER KERLEY considered abscess of the lung to be a comparatively rare disease, and it was of paramount importance to determine the mode of infection; the picture was only slightly altered according to the nature of the infection. In about 5 per cent. of cases more than one abscess was present in the lung. The radiographic findings constituted a good guide to the best treatment and to the prognosis, and X ray pictures should be taken at intervals. A lipiodol injection should always be made. The differential diagnosis could be very difficult; in some cases it could only be made by a correlation of the clinical and the radiological findings. Though a rare factor, syphilis should always be borne in mind.

Mr. V. E. NEGUS spoke as a laryngologist in favour of the bronchoscopic diagnosis and treatment of lung abscess. It was his view that every case of even suspected lung abscess should have such an examination carried out; before this was done it was impossible to say which cases would be improved or cured, and no harm could follow the skilful use of the bronchoscope. Only local anæsthesia was needed. Parenchymatous abscesses did not communicate with

TREATMENT OF PARALYSIS.

Mr. E. S. Brentnall spoke of the treatment of the disease once paralysis had appeared. The last few years, he said, had seen little distinct advance in the measures available for combating the results of severe paralysis, but they had witnessed the thoughtful evaluation of existing methods. It was also not to be forgotten that a much more adequate accommodation in country hospitals had become available in the last few years for the treatment of paralysis throughout its acute and convalescent stages, with additional provision for its subsequent after-care near the patient's home. Complete rest, with muscular relaxation and support, in a full length plaster-of-Paris bed was the most effective and simple means for dealing with the acute stage, and gave adequate protection against almost all deformity. Among the various physical measures appliable when the tenderness had gone, unloaded re-education was of overwhelming importance. The support of the affected muscles was only to be discarded when tentative freedom produced no interruption or impairment of recovery. As to the time for allowing weight-bearing, Lovett had shown that that was a most critical question for the patient with lower limb paralysis, and still more when spinal or abdominal weakness existed. Operative treatment was required in many cases to supplement conservative measures. The stretching of contractures by traction or by a series of corrective plasters was mentioned as being not only a now more popular, but a more rational procedure than sudden correction by division of the tight structures, though at times the rapid method was inevitable. Still later, operative treatment became necessary in order to improve the voluntary control at certain points, or otherwise to give stability and balance. Little progress seemed to have been made of late years in the treatment of paralysis of the upper limb. In a restricted field, tendon transplantation had proved of very considerable value, particularly in the case of the hand, but it appeared to have failed, or almost so, at the elbow and shoulder. In the lower limb tendon transplantation in general was disappointing as an isolated means of controlling paralysis.

Mr. Robert Ollerenshaw demonstrated, by photographs and radiograms, his technique in transplantation of the long extensor tendons of the toes in cases of pes cavus, a method which he considered much superior to the other methods in common use. He also showed radiograms of the operation of stabilisation of the foot combined with a posterior "bone-stop," as advocated by Campbell, and pointed out its great value in cases of "dangle foot" which had an active quadriceps extensor.

Mr. S. M. Milner drew attention to what, in his opinion, should be one of the aims of treatment in infantile paralysis—namely, the elimination of splints. Much could be done by surgery to stabilise flail joints; spinal fusion as carried out by Hibbs has much to recommend it, as eliminating a heavy spinal support. In the foot astragalectomy was advised as carried out by Whitman in the cases for which it was suggested (calcaneo-valgus deformity).

Dr. D. Sage Sutherland referred to a case in which paralysis was present which had been successfully treated with horse serum.

Dr. F. R. Ferguson asked whether convalescent human serum or any form of potent serum was available in England for use in the event of an outbreak of poliomyelitis. He also wondered in how many cases Dr. Fairbrother had been able to test the value of this immune horse serum.

The President asked on what evidence Dr. Fairbrother based his view that the spread of the virus took place by the motor pathway, and how the virus reached, as it undoubtedly did, the posterior root ganglia?

Dr. Fairbrother in reply said that unfortunately there was no organisation in this country which maintained a supply of immune serum. Only a few cases had been treated in this country with immune horse serum, but in each instance marked improvement was observed. The number, however, was too small to be of any practical importance.

ROYAL SOCIETY OF MEDICINE.

SECTIONS OF MEDICINE AND SURGERY.

On Feb. 3rd, with Dr. H. Morley Fletcher President of the Section of Medicine, in the chair these sections joined in a discussion on the diagnosi and treatment of

Abscess of the Lung.

Dr. R. A. Young said that improved diagnosi showed abscess of lung to be more common that wa formerly supposed. It might arise in one of severa ways, and it was important to determine the manne in which the suppurative process involved the lun tissue, for this would greatly influence the line c treatment. The condition might follow inhalatio of foreign bodies or of infective material into bronch especially during nose and throat operation and was then usually localised in the upper lob Secondly, it might originate in the lung parenchym from what was often called pneumonitis. A thir form was embolic abscess, which was usually multip and occurred in septicæmia, especially right-side infective endocarditis, and as a result of such remot processes as otitis, appendicitis, and infective thromb phlebitis. There were, fourthly, abscesses fro extension of suppurative processes from mediastinu bronchi, abdominal organs, or vertebræ. Agai lung abscess might result from the breakdown new growth or from necrotic changes in adjace lung tissue caused by an obstructed vascular suppl These abscesses, constituting about 10 per cent. the whole, were often in unusual situations and so we a common source of confusion in diagnosis. Finall lung abscess might result from perforation of che wall, involving fracture of ribs. Gangrene of lu occurred under conditions in which the infecti agent was especially virulent, or the patient w debilitated.

Abscess was most often simulated by interlob empyema. Bronchiectasis might cause difficulty, b lipiodol usually established its presence. New grow was difficult to exclude, and might coexist wi abscess. Radiography with the use of lipiod sometimes combined with bronchoscopy, might gi the necessary clue. The history, in its suggestio of the cause, was very important; suspicion abscess should always be aroused if there we fulminating pulmonary symptoms after operations o the nose and throat, or after a foreign body had bee inhaled, or if there was increasing fever and expector tion of pus in cases of delayed resolution followin pneumonia. Pulmonary symptoms during the cours of malignant endocarditis, or in septicæmic or pyæmi conditions, might indicate abscess formation. Bu at the end of November. No disease entailed a larger pecuniary loss by absence from work and decreased efficiency. Colds were least common at the two extremes of age. An investigation of students at Cornell University had suggested that the general physique and physical defects in cold-susceptibles were much the same as in others, and that cold-susceptible students gave a history of more infectious disease, asthma, and hay-fever than did normals. The report gave no support to many treasured ætiological fetishes.

The possible ætiological factors were atmospheric causes, cold, disturbance of metabolism, and infection. The French believed strongly in cold as a cause of colds, but Arctic explorers and other people exposed to cold disproved this theory. V. S. Cheney regarded a cold as a mild acidosis, and denied that it was infectious at all. The speaker was glad that treatment was not standardised, for every man got his cold in his own way, according to his general and local predisposition. Every case began as an acute sinusitis, and should be treated at once by rest in bed for 36 hours to three days, with warmth to the head, and wide open windows, the avoidance of all lotions and sprays, but the use of simple inhalations. Drugs should only be used to relieve symptoms—the relief given by salicin and similar preparations was well known. When the discharge became purulent, simple saline lavage was indicated.

Colds were unknown in sanatoriums, but inmates of these institutions were more liable than other people to peculiarly severe colds as soon as they returned to normal life. Light treatment and vitamins had been tried in America and proved to have no effect.

The cold was one of the penalties paid for civilisation, and might be a device of nature to vaccinate us against more serious evils.

BACTERIOLOGY OF THE COLD.

Dr. **John Freeman** said that bacterial infection could be proved in all colds, the causal agents being pneumococci, streptococci, Pfeiffer's bacilli, diphtheroid bacilli, Friedländer's bacilli, micrococci, and staphylococci. These occurred in little epidemics throughout the catarrhal season. In the later stages of a cold the mouth showed an overwhelming growth of one or perhaps two organisms; in the early stages the watery discharge might be free from bacteria. The infections were so multiple that many attempts had been made to find an earlier primary infection; Dochez had gone near—if he had not reached—proof of a filtrable virus. The differential diagnosis of catarrhal conditions was still in a very early stage of development. Until the mechanism of a disease was known, its clinical classification must be provisional. The common cold was undoubtedly an infection.

In Dochez's experiments the virus seemed to differ from that of influenza, and to protect the chimpanzee for about three months. It incited the growth of bacteria living in the mouth at the time. We did not yet know whether the virus caused all colds, whether it was single or multiple; whether it was alive or a ferment. By itself it seemed to be trivial as a pathogenic agent; it was the secondary bacteria that did the damage and caused the danger. Therefore therapeutic policy at present was directed against the bacteria. Any antiseptic strong enough to harm the bacteria would damage the nasal passages; mild douches deprived the patient of the natural defences of his nasal discharge. Room-spraying was a psychological treatment. Dochez's experiments had shown that his volunteers were very apt to develop colds when they thought they ought to.

Vaccines seemed eminently the treatment of choice. A big enough dose must be given for prophylaxis, and this dose in the middle of the catarrhal season was likely to produce a cold. The dose must therefore either be given before the season or must be built up slowly. Septic foci meant carrying infection, and should be dealt with by vaccine therapy for the sake of the patient and of his neighbours.

DISCUSSION.

Dr. **Dan Mackenzie** said that the common cold lay at the back of most of the inflammatory conditions that the oto-rhino-laryngologist had to fight. The whole subject was vague. The key to the position from the epidemiological point of view was probably the carrier; the carrier might, however, have no obvious disease between attacks. His experience of vaccines had been disappointing, and he was convinced that "hardening" treatment was fundamentally wrong for the carrier. He doubted whether the open window was the right thing for him either. The cause of adenoids was unknown, but children naturally curled up under the bedclothes; Sim Wallace had asked whether cold might not be the cause of adenoids in the English child. For curative purposes, ♏ 5 of collosol iodine in a glass of water had proved empirically very successful in colds.

Dr. **P. Watson-Williams** distinguished between common colds and the chronic or established catarrhs, the sequelæ of acute catarrhs that did not end in recovery. In many families a parent was the perpetual source of infection, the infectivity being obscured by acquired immunity. Various anatomical defects played a part in establishing chronic catarrh. The symbiosis of infecting organisms also played a part in increasing virulence beyond normal resistance. While the ordinary common cold might be treated by the physician, the subjects of chronic catarrh and asthma should be investigated by the laryngologist. The best abortive remedy in colds was a massive dose of the hydrobromate of quinine—grs. 12–20; such remedies 24 hours too late, however, did more harm than good.

Mr. **Herbert Tilley** pointed out that the sinuses were always involved in the common cold; later the infective process tended to become localised, and discharge might be pent up. Neuralgia in the course of an acute cold was nearly always due to sinus infection; the diagnosis was confirmed by finding the middle meatus blocked by œdematous mucous membrane. A little cocaine and adrenalin placed in the region for three or four minutes and applied again three or four hours later would stop the process of obstruction. If the treatment could not be repeated, the area should be scarified when first seen. Middle-ear infection was one of the dangerous sequelæ of the cold. A dose of calomel, followed by a saline, and measures for local relief of pain (glycerin and boric acid or opium), with incision of the drum, was usually successful. The speaker advocated puncturing the drum as soon as it was inflamed, and not waiting for bulging, when it might be too late.

Dr. **Bedford Russell** recommended cocaine to reduce the swelling of the mucosa as a preventive measure against sinusitis.

Sir **Thomas Horder** briefly replied.

a bronchus. A suction tube could be passed through the bronchoscope into different bronchi, to see if it would strike pus. If the search was negative, the case was unsuitable for bronchoscopy. In another type the abscess communicated with a bronchus, the latter being plugged, so that drainage was impossible. The bronchoscope was useful here, but its use should not be continued unless definite improvement was evident. In another type the patient was coughing up pus, but not freely. He referred to a patient who had had a chronic lung abscess for 12 years. He had had eight cases of lung abscess due to the inspiration of a foreign body, and in all of them removal of the foreign body brought about cure.

Dr. L. S. T. **Burrell** referred briefly to lung abscess following operations on nose, throat, and teeth. There were four methods available: (1) to leave the patient alone, (2) to treat with a bronchoscope, (3) to drain surgically, (4) to induce pneumothorax. Looking through his cases he was impressed with the seriousness of lung abscess, and how impossible it was to advocate one method of dealing with all the cases. Bronchoscopy should not be done in cases where there was a foreign body. He was appalled by the number of people with lung abscess who appeared to do well but eventually died. Surgery, he thought, had not yielded the results which were expected of it. And the induction of pneumothorax he regarded as extremely dangerous in the case of superficial abscess. The safest treatment for an abscess which was central he believed to be collapse at an early stage.

Mr. A. **Tudor Edwards** emphasised the fact that there were two types of symptoms in abscess of lung. There was a type in which the discharge from the abscess was continuous, and that was often confused with bronchiectasis. There were two types of effusion secondary to pulmonary abscess: one was the chronic, slow-forming localised empyema; these did very well. A different condition was that in which fluid collected in a large pleural cavity with almost no adhesions. Cerebral abscess did occur in relation to undrained lung abscess. He was becoming more convinced that drainage in these cases should be done in two stages; in the first, an adequate amount of lung tissue should be taken away, and in the second he used diathermy of lung with a button electrode. This latter prevented the projection of emboli into the circulation, for the vessels were sealed by the diathermy.

SECTION OF LARYNGOLOGY.

A MEETING of this section on Feb. 5th, with Mr. W. G. **Howarth**, the President, in the chair, was devoted to a discussion on

Common Colds and their Sequelæ.

Sir **Thomas Horder** defined a cold negatively as not paroxysmal rhinorrhœa or sneezing, hay-fever, acute naso-pharyngitis preceding an acute disease, nor even acute coryza, though to the layman these things were all "colds." A bout of sneezing might do the sufferer good by clearing the nasal passages. The common cold might be defined as an acute specific catarrh involving the upper respiratory tract, running a benign course for two or three days, with pyrexia and other constitutional symptoms, and protecting the patient for a short time only. Probably there was a specific infection due to a filtrable virus, associated with secondary infections by catarrhal organisms. The term "feverish cold" was justified by the inadequacy of clinical and bacteriological knowledge. The fewer organisms that could be demonstrated, the more safely the common cold could be diagnosed. Rhinitis, sinusitis, Eustachian catarrh, and pharyngitis all occurred in the type case, but individuals varied in the anatomical distribution of the infection. The disease might be trivial or devastating, and the toxæmia might be deep. There were also abortive cases. There was no evidence that the infection known as the common cold ever expressed itself as a chronic catarrh. Among the alleged predisposing causes were heredity, rheumatism, and gout, but these were very doubtful. The seasonal and age incidence were recognised. Exciting causes did not include mere cold or mere heat, but rapid changes in temperature might aid the specific materies morbi, which was probably a filtrable virus. The nearest solution to the difficult diagnostic problem presented was a careful clinical investigation.

Prophylaxis included general methods of preventing lowered resistance and cleaning the atmosphere; local disinfection, isolation, and inoculation. The belief that a "fit" and hard person was less liable to colds had much against it; many people developed colds on return from a holiday. Fitness did not protect against the primary infection, though it did help the patient with the secondary infections. Everyone would agree that physiological breathing should be taught, and unhealthy conditions of the nose and pharynx corrected, but there was no agreement on the best local prophylactic measure, and no evidence to support any one method. Isolation was important, but unfortunately the equally infectious mild case went free. Inoculation could only be empirical until the causal agent had been isolated. Curative treatment should begin at the earliest possible moment, and in many cases the cold could be aborted by a hot bath, copious hot drinks, a smart purge, a warm bed, and opium. After these, the subsequent treatment did not greatly matter, but the patient's faith in any given remedy should not be scouted. As the disease progressed, the treatment of the patient became more important and the treatment of the nose less important. Time alone could show the value of the numerous specific remedies now on the market. It was the duty of the profession—and of those who pressed these remedies on it—to maintain a healthy scepticism, and to promote research.

A LARYNGOLOGIST'S VIEW.

Sir **StClair Thomson** said that his researches in collaboration with Prof. R. T. Hewlett, 37 year ago, had stood the test of time. They had demonstrated that the ciliated epithelium of the nose filtered off as many as 14,000 organisms in one hour's quiet breathing. The common cold was an infectious disease, and might be apostrophised in the words of Matthew Arnold:—

> "Others abide our question. Thou art free.
> We ask and ask. Thou smilest and art still,
> Out-topping knowledge."

As had been wittily said, the common cold lasted a fortnight, but if treated it only lasted 14 days. It might be defined as an acute or subacute catarrha affection, commencing in the nose or post-nasa space, generally invading the sinuses and sometimes spreading to the Eustachian tubes, pharynx, larynx or further. Its greatest frequency was in the latter part of January, declining thence to the latter half of June, increasing sharply at the end of July, to reach a peak at the end of September, and another welcomed the search for a classification that, while not a mere pigeon-holing, endeavoured to study the actual causal factors determining reaction types.

Dr. David Forsyth said that he had never been able to regard the oral-libidinal as necessarily preceding in time the anal-libidinal primary; the child must experience both from the very beginning of life. The "oral" child became a much pleasanter, more educable and extraverted type of child than the "anal" type. It was a matter of very great importance which zone came to occupy the child's chief interest.

Dr. Margaret Lowenfeld asked whether any research had been done in relating later developments with early life-histories in this connexion: for instance, the subsequent fate of children who had at first refused to suck, thus throwing great stress on the anal experience, and the relation of subsequent speech defects to oral impulses in the earliest days.

Dr. Henry Yellowlees said that Dr. Glover's views dealt a death-blow to the belief that neuroses were in any sense halfway houses to the psychoses. The objection to this classification was that no case could be assigned to its class without elaborate investigation; it did not help the clinical worker.

Mrs. Melanie Klein said that the effect of a good sucking stage could be observed to influence the subsequent development, modifying the sadistic impulses.

Dr. Glover, in reply, pointed out that the primacies were cross-sectional views, and at each cross-section one interest would be found predominating. In longitudinal section they would be found overlapping, and one influenced another, the anal being largely conditioned by frustration of the oral, for instance. He thought his scheme, while appearing at first sight impracticable, might lead to much combined research between clinicians and psychoanalysts. Psychiatrists had got off too easily in the past; their classification compared with the stage of organic medicine in which diseases were classified by the region in which symptoms appeared—the head, the leg, the belly, and so on. The physician did not find the modern complex classification impracticable, because he had got used to it.

MEDICAL SOCIETY OF LONDON.

Mr. Herbert Tilley took the chair at a meeting of this society on Feb. 8th, and Mr. Harold Dodd opened a discussion on the

Toxic Syndrome of Chronic Cholecystitis.

He said that the condition was more common than was generally realised, and that it formed an appreciable proportion of the obscure conditions classified by Mackenzie under the two headings of diseases recognised by a single symptom and diseases with uncoördinated symptoms. The incidence favoured women in the proportion of two to one. He differentiated sharply between chronic cholecystitis and gall-stones, which were often a late sequela. Many of the ailments in the syndrome might appear to be quite unrelated, like the parts in a jig-saw puzzle. The family history sometimes showed near relatives suffering from similar conditions. The trouble could often be dated from the birth of a child, a severe febrile disease, or a long history of bilious attacks, sometimes dating from infancy. In some cases there was a history of maternal ill-health during pregnancy. Jaundice occasionally occurred.

Unpleasant changes in the sleep were constant; all the patients were nervous and dreadfully miserable. Neurasthenia was prominent and especially common in single business women of about 30. Irritability and giddiness were general. The headache was characteristic, usually across and deep behind the eyes, sometimes in the occipital area or nape, or in the frontal region towards the vertex. Breathlessness was often prominent, occurring after exertion and food and in the night. It was sometimes associated with sensations of suffocation or a deep aching pain in the upper part of the right chest. Some cases of asthma were relieved by a gall-bladder operation. Pain, discomfort, and catches in the breath at the right costal margin and the right lower intercostal spaces were frequent and might be the chief symptoms. Palpitation and thumping of the heart were common and might be accompanied by pain about the heart. Patients of any age or sex might have cold shivers or hot flushes, and all were very susceptible to changes of temperature.

Among the alimentary symptoms were capriciousness of appetite and nausea. Patients could not take fatty or acid food, and ultimately reached a stage when bread and butter and boiled fish were the only foods which did not provoke severe indigestion. Many complained of a dry mouth with a nasty taste, which might lead to air-swallowing. Soon after taking food, discomfort grading to severe pain occurred in the epigastrium; at first only after the chief meal of the day, but later after every meal. Flatulence was outstanding and distressing in all stages of the disease. Some patients had hæmatemesis. Periods of freedom from pain gradually became shorter until there might be daily discomfort and two or three attacks of pain in a fortnight. The pain occurred one to three hours after food and might awaken the patient at night. It was sometimes associated with a small duodenal ulcer, always situated on the anterior wall half an inch from the pylorus. Constipation was usual. Scalding and sometimes frequency of micturition occurred on and off. Rheumatism and neuritis were common complaints, occurring in all parts of the body. The general strength was usually much lessened and, in the later stages, loss of weight was the rule. Occasionally the thyroid was symmetrically enlarged, less often irregularly. Symptoms increased at the menstrual period in a considerable number of patients.

The physical signs included an appearance of tiredness and anxiety. The eyes were distinctive: they appeared watery, with muddy sclerotics and slight injection of the conjunctival muscles. Moskowicz's sign—dilatation of the right pupil when the eye is at rest—occurred fairly often. The skin was usually of a greyish-bronze or sallow colour. Hyperæsthesia was present in 75 per cent. of patients, and tests for it helped to localise the site of the toxic focus; it was usually over the right half of the abdomen, occasionally in the right iliac fossa, and, in the back, below the angle of the right scapula to the crest of the ilium. Boas's sign was reliable: tenderness on pressure over the right costo-vertebral angle; sometimes this pressure evoked also the ordinary pain and flatulence. The tension of the back muscles between the twelfth ribs and iliac crests was often unequal. There was usually tenderness over the gall-bladder area, in the right rectus and in the right iliac fossa; often also in the left iliac fossa, probably due to spastic colon. Piles were

SECTION OF PSYCHIATRY.

AT a meeting of this section on Feb. 9th, the chair was taken by Dr. BERNARD HART, the President, and a paper on the

Principles of Psychiatric Classification

was read by Dr. EDWARD GLOVER.

The psycho-analytic worker, he said, could not postpone for ever the task of correlating his formulations with psychiatric classifications. Psycho-analysis looked forward to an increasingly close alliance with pure psychiatry. Almost all thoughtful text-books drew attention to the difficulties and confusion of existing classifications—which gave an impression of matted complexity, a complexity which was in inverse ratio to the fundamental understanding achieved. An adequate system should be elastic enough to allow modification and indicate the possibilities of future research. It should present existing data in as comprehensible a light as possible, but should not force explanations on little-understood problems. A purely descriptive method was dangerous and retrogressive; it was unlikely to be either accurate or complete in view of the existence of unconscious elements. In the absence of general agreement on ætiology, however, a descriptive factor seemed inevitable, at any rate temporarily. To it could be added other factors which would amplify it and—most important—relate the phenomena of psychiatry to normal development. A sound classification must be built up in close relation to the development of the ego structure, and in particular to that phase during which the regulation of instinctual tendencies swung between the great primitive mechanisms of introjection and projection. This second factor must be supplemented by a third—a specific factor that would distinguish what the man in the street meant by madness—the psychoses—from other psycho-pathological phenomena. The closest approximation to a specific factor was loss of sense of reality—a disturbance of ego-object relation.

The speaker took three groups under his descriptive factor: a schizophrenic group characterised by withdrawal from reality, a depressive group, and a delusional group. The function of the ego was to effect a compromise between the demands of instinct and the possibilities of reality. The signal system by which the ego tested the success or failure of its manœuvres was anxiety. Anxiety was the alpha and guilt the omega of human development. The three possible manœuvres were sublimation or repression of the demands; lessened demands with some tolerance of frustration; and distortion of the ego. To the third group belonged the psychoses and neuroses. The ego, however well organised, was essentially a composite, even in a young child; from at any rate one year onward the ego was polynuclear. The earliest ego tendencies were derived from scattered instinctual elements, and gradually converged. The elements of the first primitive nucleus included all the erotogenic zones, together with all the aggresive centres, as well as the oral libidinal system. The fixation point of melancholia was oral; it would ere long be possible to determine the fixation points of schizophrenia. The last organised fixation points represented the neuroses. There was a great field for research here.

LOSS OF REALITY—PROVING.

There was much scope for confusion about the boundary between the ego and the object, since in auto-erotic phenomena the object was part of the subject's own body. An instinct that could be satisfi in the subject's own body was to some extent manag able; one that required a separate object was mo difficult to master and was more likely to cause t psychic pain of frustration. Some colics could relieved by expelling wind or ejecting a crumb i.e., a "me" pain could be converted into a "not me Here was the basis of the projection phenome of paranoid states. The ego would be much saf from anxiety if it could convert pleasurable "no me's" into "me's"; if the desired object could introjected into the ego. This was the basis of t introjection mechanisms seen in schizophreni Inside the ego were the "pins" and "crumbs of frustrated instinct, complicating the processe When the pleasurable object was found to be n really a part of the ego, but only occasionally availabl it became hateful; but to destroy it would be "kill the goose that laid the golden eggs." Henc there was serious tension. The child struck th bars of its cot and at the same moment the ba "struck back" hurting the child—here was the ger of persecutory ideas. Introjection was a mechanis for dealing with disappearing objects; whether th child loved or hated an object, the object was bes dealt with if it could be got inside. Unfortunately, th result was often to get the ego's own head "i chancery" instead of the object. Hate raged agains hate—the seeds of melancholia.

The mechanism of repression broke the viciou circle by sacrificing the primitive instinct; thi process was the development of the super-ego. Th child longed for a real reality, free from the terrifyin results of projection. The function of parents wa to provide a reassuring reality in this phase. Th normal infant was in an acute psychosis and woul continue in a state of anxiety unless it could come t terms with reality. If, in later life, repression brok down he would be plunged back into infantile anxiety The potential psychotic was one who had a precariou adaptation to reality. Adult reality sense represente the capacity to maintain contact with objects, th objects through which infantile instincts were gratifie and all possible substitutes. Society was not to exacting in its demands so long as a man did no try to kill his introjected enemies by suicide or hi projected ones by homicide.

The main psychoses and neuroses could be classified by ego relations with objects quite simply in children, but in adults the classification would have to include certain character-states and formations not usually grouped with psychoses and neuroses. Introjective oral phases were linked with dementia præcox and melancholia; anal phases with obsessional states, and genital phases with hysteria and psycho-sexual inhibition. The projective oral phases were linked with the schizoid and paranoid group, the anal phase with drug addictions and compulsive character groups, and the genital phase with the anxiety character and social inferiority group. In the oral and anal phases there were essentially group fixations, not single. The schizophrenic fixation was an omnibus fixation and had components from both introjective and projective sides. Compulsive neuroses were obviously autoplastic, but some phobias had a paranoid element. Drug addictions were on the borderline between psychoses and neuroses, but on the whole, the term "borderline" was unsatisfactory, and the term "potential psychosis" was preferable.

DISCUSSION.

The CHAIRMAN said that the history of psychiatric classification was strewn with wrecks, and he

REVIEWS AND NOTICES OF BOOKS

The Laboratory in Surgical Practice.

By E. C. DODDS, M.V.O., M.D., Professor of Biochemistry, University of London ; and LIONEL E. H. WHITBY, C.V.O., M.D., M.R.C.P., D.P.H., Bacteriologist to the Middlesex Hospital. London: Constable and Co., Ltd. 1932. Pp. 187. 8*s*. 6*d*.

WE welcome this, the first of a new series under the general editorship of Gordon Taylor, because it fills a need. Hitherto if surgeons have desired to obtain information on the numerous tests employed in their work, they have had to consult the scattered literature or large technical laboratory manuals. Here, in simple language, Prof. Dodds and Dr. Whitby have described and explained the methods of performing such tests as those of renal function, blood grouping, and basal metabolism. They have ably summed up the occasions when such tests are called for and likely to give useful information, and the significance of the results that may be obtained. The sections on cholecystography and intravenous pyelography are especially useful, and those on the uses of serums, vaccines, and the bacteriophage are very informative.

We commend the book both to working surgeons and to members of laboratory staffs.

Der Mineralbestand des Körpers.

By WOLFGANG HEUBNER, Professor in Heidelberg. Berlin: Julius Springer. 1931. Pp. 94. R.M.8.50.

THE proportion of mineral constituents in the bodies of vertebrates is small in proportion to the so-called organic matter—in man it is about 4 per cent., as measured by the ash left after incineration. About a quarter of this is associated with the soft tissues and body fluids, the remainder being in the bones. Prof. Heubner's book, which is a reprint of the chapter of the same title in the " Handbuch der normalen und pathologischen Physiologie, Bd. XVI/2 " is a useful up-to-date summary of our present knowledge of the significance of the inorganic constituents of the body. In his introductory chapter he calls attention to the interesting fact that, small as is the mass of mineral constituents relative to the " organic " —e.g., the proteins—yet, owing to the enormous molecular (or micellar) weights of the organic matter (multiples of 35,000), the molar concentrations are often greater. Thus the concentration of hæmoglobin in the blood corpuscles is 0·02 molar, whilst that of chlor-ions in the plasma is 0·1 molar.

Brief sections deal with the anions and kations in the blood and other body fluids. The remarkable excess of bases over acid radicles (recognised as such) in blood which has variously been attributed to the acidic properties of proteins and the presence of unknown acids is discussed. The author says truly : ‘ Es ist von grundsätzlicher Wichtigkeit dass die Frage der Absättigung des Basenüberschusses im Blutplasma durch weitere Untersuchungen zu endgültiger Klärung gebracht wird." Sections follow on the mineral content of the blood corpuscles, of the whole blood, and of the solid tissues of the body.

It is remarkable that whilst the composition of the ash of the blood plasma of all mammals is very similar (although in amphibians more dilute than in land animals), the ash content of the corpuscles varies among different animals, and is characteristic for each kind.

Prof. Heubner alludes to the elements, such as copper, manganese, iodine, vanadium in various ascidians, which, although present in very small quantities in the fluids or tissues of the body, appear to have important functions in maintaining it in a state of health. He mentions interchangeability of certain elements—strontium will to some extent replace calcium in the bones and bromine will take the place of some of the chlorine—but refrains from a full discussion of the rôle of these interesting constituents of the body.

This concise work forms a valuable handbook for those interested in this branch of biochemistry. A copious bibliography is supplied in footnotes.

A Text-book of Exodontia.

Second edition. By LEO WINTER, D.D.S., Professor of Oral Surgery, New York University College of Dentistry. London: Henry Kimpton. 1931. Pp. 455. 42*s*.

THE term exodontia was coined in America as a substitute for the more homely expression, extraction of teeth, current in this country. Several books on this subject have been written by American dental surgeons within the last few years. This book is a fair but not outstanding specimen. It is a safe guide as far as it goes, but in spite of its length many omissions are apparent—for example, post-operative treatment, which from a practical point of view is of paramount importance. An operation such as the removal of an impacted lower third molar may be one of considerable severity. The after-pain may be great, and the success of the operation in the eyes of the patient is largely conditioned by the ability of the operator to control this pain. Very little is said by Prof. Winter on this aspect. A few drugs are recommended, but no hints are given on the value of frequent irrigation, the use of heat or cold, counter-irritation, or other devices.

In discussing the treatment of impacted upper canines the author shows a marked preference for the palatal route. Where the canine is close to the palate, as is often the case, this route is obviously indicated. But when a canine involves the antrum or the nasal fossa, there is much to be said for using the alveolar path. In connexion with the treatment of infected lower third molars, infiltration injection is rightly condemned on the grounds that the injection would necessarily be made into an infected area. We cannot, however, agree with the advice to use conduction anæsthesia, for the needle would have to be inserted close to the inflamed area, and though less the risk of infection would still exist; a general anæsthetic avoids this danger. No mention is made of the removal of the upper third molar as a speedy means of relieving the pain from an infected lower third molar. This is not always effective, but in many cases much of the pain is due to the fact that the upper molar bites on the inflamed and thickened pad of gum overlying the lower molar. The extraction of the upper tooth is a simple matter and may relieve the pain so as to enable removal of the lower molar to be delayed until the inflammation has subsided. We note with interest that Prof. Winter regards the removal of a lower second molar as a common. A positive radiogram was not necessary. The barium meal might show a change in gastric tone or emptying rate, an irritable duodenum and occasionally a pathological appendix. In time early cases might be treated medically, but at present operation was confidently advised. Improvement began immediately, and convalescence lasted for 6 to 12 months with occasional slight relapses. A holiday was very desirable, and sedatives and vitamin-containing preparations should be prescribed.

Mr. Dodd described the anatomy and neurology of the gall-bladder, and also the appearance of a diseased gall-bladder on the operating table.

THE PATHOLOGICAL ASPECT.

Dr. Arthur Davies said that most specimens showed definite histological signs of medical cholecystitis: the mucosa was œdematous and the wall was infiltrated with lymphocytes, histiocytes, plasma cells, and young fibroblasts, and there were inflammatory changes in the subserous layer. His impression was that in the majority the route of infection had been the blood stream. The specimens showed sinuses formed by the pouching of the mucosa into the muscular tissue; in one case small gall-stones were found in the interstitial substance. In 12 per cent. there were definite indications of strawberry gall-bladder. In a number there was no evidence of histological change; he believed that in some gall-bladders change of function must occur without change of structure.

Dr. Charles Miller said that the gall-bladder might be blamed for certain cases of urticaria, asthma, migraine, and gall-bladder dyspepsia. There was a constant difficulty in determining the relationship between pain produced by the gall-bladder and pain produced by the heart—between angina pectoris and gall-bladder colic. The quality of the pain might be almost identical, and the similarity might be due to an origin in the same region of the central nervous system. From a study he had made of the post-mortem records of 350 patients at the London Hospital with gall-stones or cholecystitis, he had found an excess and earlier incidence of atheroma in patients with gall-bladder disease. Chronic gall-bladder disorder might therefore produce especially severe cardiac symptoms in a middle-aged heart that was more degenerated than it should be, and these symptoms might be relieved by cholecystectomy.

THE RADIOLOGICAL ASPECT.

Dr. G. E. Vilvandré stated that in careful hands with proper technique at least 70 per cent. of gall-stones could be shown by the radiologist. The dye test might fail to reveal a pathological gall-bladder, but a visible gall-bladder, whether it had stones or not, was pathological. Negative radiological evidence was worth nothing. A good clinical history was a valuable aid to the finding of gall-stones. Investigation of the gall-bladder should be an essential part of every routine gastro-intestinal examination.

Dr. J. R. Wylie described his radiological research into early duodenal ulcer before the appearance of deformity; these "observation" cases might present a difficulty of diagnosis from cholecystitis. This class of case had no ulcer crater, but a regular peristaltic action in the first stage of the duodenum, with considerable tenderness. The peristalsis had until recently been put down to a reflex action from the appendix or an inflamed gall-bladder, but the speaker thought that there might be a typical local lesion in the duodenum. The only reflex action that he could associate with the gall-bladder was a pyloric spasm.

Mr. Zachary Cope suggested that Mr. Dodd's jig-saw puzzle could be put together to form several alternative pictures. There was probably no one present who had not had one part of the syndrome, but if all the syndrome had to be present, then probably no one had it. He asked for a more precise definition of the syndrome. It was very difficult to associate this syndrome with serious demonstrable organic disease of the gall-bladder. The syndrome was seen in the neurasthenic type, which Mr. Dodd had put down as neurotic—a very dangerous generalisation. The same symptoms had been attributed to chronic intestinal stasis. The essential point of criticism was that in many cases with the symptoms described the liver was at fault. Many patients relapsed some months after operation. Mr. Cop said that he would have been more convinced if h could have known the state of the liver of Mr. Dodd' patients, and the state of the patients five years ago

Mr. A. J. Walton urged the necessity for grea care. It was now becoming fashionable to remov the gall-bladder, as it had formerly been to remov the appendix or fix the colon. He believed that large number of cases with the syndrome Mr. Dod had described were obscure cases of hepatitis; the might be pathological cholecystitis, but were certainl not surgical cholecystitis, and were readily cured b medical means. It was necessary to strike a balanc between credulity and disbelief in the value of th cholecystogram. He would remove a gall-bladd only if it had lost its normal colour and was definitel thickened to the feel or contained gall-stones.

Dr. W. Langdon Brown asked what was th irreducible minimum of the symptoms for a positi diagnosis. He thought that many of Mr. Dodd cases could have been cured without operation, an doubted whether all had really had cholecystitis.

Dr. A. H. Douthwaite said that a large proportic of Mr. Dodd's hyposthenic type were suffering fro visceroptosis, and could be cured by exercise ar ordinary medical treatment. Cholecystitis could treated by draining the gall-bladder and abdomin exercises. He challenged Mr. Dodd to a conte between these methods and surgery. The hyposthen person was liable to angina, and the confusi between this and cholecystitis often gave rise mistaken diagnosis. Nevertheless, there were patien with angina whose gall-bladders were abnorm radiologically and who benefited by their remov probably because they were a toxic focus.

Dr. C. E. Lakin asked if the specimens had be examined bacteriologically.

Dr. Charles Newman said that the syndro fitted the gall-bladder dyskinesias, and describ recent work done on the Continent. Diagnosis w easy by duodenal intubation and the test with pituita extract and olive oil, and the medical treatment w simple and effective.

Mr. Dodd, in reply, promised a later report on t progress of the patients. He required the physic signs to be definite before he operated. On average, four to six of the groups of symptoms nervous, respiratory, cardiac, alimentary, urinar and locomotor—should be represented. He doubt Mr. Walton's assertion that many patients could treated medically. Dieting was impracticable becau the patients could hardly retain any food.

Dr. Davies replied that unfortunately no bacteri logical investigation had been done.

PNEUMONIA

Excellent results have been obtained in the treatment of Pneumonia with **OPTOCHIN BASE.**

OPTOCHIN BASE (Howards) is Ethylhydrocupreine Alkaloid—a synthetic derivative of Quinine with a marked bactericidal action upon all types of pneumococcus.

Given orally, in tablets or powder, **OPTOCHIN BASE (Howards)** is well adapted for use by the General Practitioner and is of great value in Pneumonia of children and adults.

May be obtained through usual trade channels.

means of relieving the impaction of a third molar, as malpraxis. Some dental surgeons hold with him that an impacted lower third molar must itself be removed at any cost; others tend to deal with every case of impaction by the routine removal of the second molar. The first group inflicts on the patient a long, tedious, and often painful operation, which might sometimes be avoided by the simple removal of the anterior tooth; the second group may deprive the patient of a useful tooth without removing the infected one, or eliminating a source of infection which may continue to give rise to trouble. In our view both methods of procedure have their place, according to the conditions which may be present.

The last chapter, on the removal of cysts, leaves much to be desired. Nothing is said of those cysts, not uncommon, which impinge on the antrum without opening into it. The removal of the lining membrane, as advocated by the author, would involve the antrum in these cases, and it is far better practice to leave the lining in the deeper part of the cyst intact. Provided that a sufficiently large opening has been made, there is no fear of recurrence. The closed method of operation in which the flaps are sutured after removal of the cyst is not mentioned. It cannot be carried out in all cases, but when suitable it is an excellent method. It is curious that the only section in the book devoted specifically to the treatment of post-operative pain follows this chapter. Yet after-pain is uncommon following the removal of a dental cyst, provided that free drainage has been established and that all sharp edges of bone have been smoothed away.

The book is lavishly illustrated with pictures of high quality. The various steps of different operations are clearly depicted, and the illustrations should prove of much help to the reader.

Rheumatoid Arthritis and its Treatment.

By VINCENT COATES, M.C., M.A., M.D. Cantab., M.R.C.P. Lond., Consulting Physician, Trowbridge and District Hospital; Physician, Royal Mineral Water Hospital, Bath; Cardiac Specialist to School Medical Service, Wilts County Council; and LEO DELICATI, L.M.S.S.A. Lond., Resident Medical Officer, Royal Mineral Water Hospital, Bath. London: H. K. Lewis and Co., Ltd. 1931. Pp. 114. 6s.

THE speed with which literature on the subject of rheumatism and arthritis is accumulating makes it impossible for the busy practitioner to keep pace. He will therefore be glad to know of this small book, which in 114 pages gives him useful and practical information. The Royal Mineral Water Hospital, Bath, provides a wealth of clinical material and a very fruitful field for observation, and it has been quite easy for the authors to collect 100 consecutive cases of rheumatoid arthritis, all of whom are resident in the hospital, and to investigate them along certain lines, with a view to forming an approximate idea of the frequency of clinical and biochemical syndromes. The book, which treats of this disease only from the therapeutic point of view, is arranged in sections. The opening chapter deals with the vexed problem of classification, and although the authors do not get much nearer to the solution of this problem, at least they define clearly what they themselves understand by rheumatoid arthritis. The second chapter contains a clinical description of the disease, which includes an interesting short history of the "subcutaneous nodule." Certain biochemical obliquities and their interpretation are next described, after which an account is given of systemic treatment along definite lines. This is probably the most valuable section in the book, which is concluded by descriptions of a number of instructive cases. This work does not set out to be an exhaustive treatise, but a description of principles and methods which, in the authors' hands, have been found useful in the treatment of rheumatoid arthritis. It will be appreciated both by practitioners and medical students.

Practical Physiological Chemistry.

Tenth edition. By PHILIP B. HAWK, M.S., Ph.D., President of the Food Research Laboratories, Inc., New York City; and OLAF BERGEIM, M.S., Ph.D., Associate Professor of Physiological Chemistry in the University of Illinois, College of Medicine, Chicago. London: J. and A. Churchill. 1931. Pp. 929. 30s.

THIS book was originally published in 1907, but since then such rapid strides have been made in this subject that this volume will be found to contain about five times as much material as the first volume. Many of the chapters have been entirely rewritten or revised, and the advice of other experts has been requisitioned by the authors in bringing the various sections up to date. Basal metabolism is dealt with at length, as are problems in connexion with blood, urine, and gastric analyses. The section on proteins has been considerably extended, and much space has also been devoted to a consideration of vitamins and deficiency diseases. In places where only a very brief outline of the subject is given—as, for example, in the chapter on the endocrine organs—many references have been supplied to indicate where more comprehensive information can be obtained. There are nearly 300 illustrations, which greatly add to the value of the text, and there is also a very useful appendix on reagents and solutions.

The book is already so widely known and appreciated that it is hardly necessary to praise the excellent way in which the author has managed to include so much of value and interest in a comparatively small volume.

The Surgeon.

By C. JENNINGS MARSHALL, F.R.C.S., M.S. London: Geoffrey Bles. 1932. Pp. 129. 3*s.* 6*d.*

THIS contribution to the Life and Work Series is written by a surgeon to a large teaching hospital who has therefore had every opportunity to reinforce his learning both by the clinical opportunities enjoyed and the necessity of imparting its essentials in simple terms to students. Here the students are the public, and the information to be given is not concerned with the practice of surgery (which must be the surgeon's job and only surgeons can appraise it) but with the relations that surgery bears to those who are to benefit by its practice. Mr. Marshall's brief exposition of the training required to make a surgeon and of the meaning of surgery; his analysis of the situations when operation should be advised; his remarks upon ethics and orthodoxy; and his historical deductions make up a small book that will be read with advantage by all men and women who wish to understand the problems, the difficulties, and the successes of modern surgery.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 13, 1932.

BCG AND LÜBECK.

The long drawn out trial of Dr. Georg Deycke and his colleagues at Lübeck in connexion with the Calmette-Guérin vaccine has at last reached its end—an end which is tragic for Prof. Deycke who, now no longer young in years, has spent a lifetime in disinterested service to bacteriology. The events which led up to the trial can be summed up in a few words. During the winter of 1930–31 253 infants in Lübeck were given by the mouth B C G vaccine subcultured from cultures received from the Pasteur Institute in Paris; within some three months 68 had died of acute tuberculosis, and doubts arose as to the nature of the vaccine. Broadly speaking, there were two possibilities. Had B C G, a non-virulent bovine strain of tubercle bacillus, suddenly acquired virulence, or had another strain of tubercle bacillus accidentally gained access to the vaccine? After exhaustive investigations the German courts have decided that the latter is the explanation, thereby vindicating the reputation for non-virulence of B C G, but involving Prof. Deycke in the responsibility, which as head of the laboratory he must accept, for the accidental admixture of virulent cultures with the vaccine. The final stage in the trial is reported by our Berlin correspondent on p. 365 of our present issue.

The questions raised by this calamity are no mere academic quibbles. The B C G vaccine has been broadcast so extensively that any bacteriologist, and indeed any clinician, may find himself suddenly confronted with the decision, whether or not he should recommend its use. We need not recount all the stages in the development of B C G by Calmette and his co-workers at the Pasteur Institute. They have been set out diligently in these columns. It is perhaps a little unfortunate that what may be called practical clinical flank of this prophylactic army was allowed to march ahead of—we had almost said get out of touch with—the bacteriological research flank. On the practical side it can be claimed that several hundred thousand infants and children have received this vaccine and that (apart from the Lübeck tragedy) the recorded deaths have been few and, as far as could be ascertained, not attributable directly to the vaccine. How far these infants have been protected from clinical tuberculosis can only be computed by the calculation of probable risks, and the variable factors are so many that this calculation cannot be worked out with any degree of certainty. On the purely bacteriological side the researches of various workers (Petroff, Malkani, Dreyer and Vollum, and others) have suggested that a return to virulence on the part of the B C G strain is not impossible. The answer to these experiments has been that the conditions of cultivation on bile potato laid down by Calmette and Guérin have been so altered that an entirely new set of circumstances has been created, or alternatively, that some workers have not been sufficiently careful in guarding against contamination of their cultures with virulent strains of the tubercle bacillus: whilst in at least one instance experiments made by one school have been repeated seriatim by another with opposite results. We cannot here thread our way through all these controversial points. In our last two issues, however, have appeared the records of a painstaking investigation in the Cambridge Field Laboratories by Dr. A. Stanley Griffith, which does much to clear the air. He has found that although B C G can produce tuberculous lesions in guinea-pigs, monkeys, rabbits, and goats, these lesions have no progressive tendency, and after a time heal or become obsolescent. The culture of B C G with which he has worked has retained its cultural characteristics and has not increased its virulence after continuous cultivation for eight years on media, such as egg, which in some hands have produced virulence. He concludes by supporting the contention of Calmette that B C G may be used as a vaccine without risk of causing progressive lesions.

This is the crux of the matter. Bacteriologists can be left to settle the academic points of the B C G controversy at their leisure; the real points at issue are (1) whether the administration of a vaccine of a living but non-virulent strain protects in a way which a vaccine of dead organisms cannot; (2) whether there are risks inherent in the use of living-culture vaccines which cannot be guarded against with reasonable precautions in a well-organised laboratory; and (3) if there are such risks, whether the dangers of tuberculosis in infancy are so great that the risks of the vaccine going wrong are worth taking. The first question is a bacteriological one which has been partially answered by Dr. Griffith's work in our current issues. The B C G strain wanes and finally dies, but in so doing creates antitoxins in animal tissues. We are not quite sure that the method of administration of the vaccine to goats and other animals is strictly comparable to that usually followed by the clinician. It is conceivable also that there is a wider variation in the constitutional powers of infants under modern conditions of life than occurs amongst even domesticated goats and rabbits. We must not be content to admit that B C G vaccine administered to infants has done no harm—Lübeck apart; we must be convinced that it has definitely conferred a valuable measure of immunity. Turning now to the second question, can the bacteriologist ensure that no untoward accidents shall happen to the living vaccine so that it shall never contain virulent organisms? At Lübeck certain important precautions were not taken, and the verdict of the court reflected the views of those who sat in judgment as to the seriousness of the neglect. Before B C G vaccine is extensively used in this country it is to be hoped that an expert committee of bacteriologists will

GLUCOSE-D

GL

A preparation of medicinal glucose in which is incorporated calcium glycerophosphate and vitamin D to assist a normal metabolism of calcium and phosphorus in conditions—notably acidosis, asthma, cyclical vomiting, heart disease, and fever—that may require both glucose therapy and the prolonged administration of a fat free, and thence fat-soluble-vitamin free, diet.

In 1-lb tins—1/9

per cent. of the total. Cases considered arteriosclerotic in origin amounted to 31 per cent., while those in which the heart failure was consequent upon hyperpiesia were 17 per cent. of the whole series. The differentiation of the last two groups is admittedly difficult, and McEachern and Baker take a blood pressure of 150 mm. of mercury as the arbitrary dividing line. If, however, the two categories are added together as "non-rheumatic," they make the largest group in the series—namely, 48 per cent. of the whole. Hyperthyroidism was responsible for some 7 per cent. of the cases, and 5 per cent. were found to be associated with chronic disease of the lungs. In only 3 per cent. was cardiovascular syphilis the causal factor—despite the fact that syphilitic aortitis is recognised in over 15 per cent. of all the patients admitted to the hospital with heart disease. The remaining 2 per cent. fall into a miscellaneous group of uncertain ætiology.

These figures are very similar to those given by W. D. Stroud, L. B. Laplace, and J. A. Reisinger,[2] who have made a parallel study of 253 cases of auricular fibrillation seen in Philadelphia. (Rheumatic, 48 per cent.: "non-rheumatic," 35: syphilitic, 9; thyrotoxic, 3·5: miscellaneous, 4·5.) The low incidence of cardiovascular syphilis as a cause of auricular fibrillation is striking especially in the first series, and it is noteworthy that of 100 cases of luetic heart disease studied by A. Friedlander[3] in Cincinnati, fibrillation occurred in only ten. McEachern and Baker consider that in nine of their 14 cases of syphilitic aortitis auricular fibrillation was produced by administration of digitalis, and in five of these normal rhythm returned on discontinuance of the drug. They report two fresh cases of fibrillation in children under 10, both of whom were suffering from rheumatic carditis, and in a review of published information on this condition in childhood they suggest that in some, at any rate, of the reported cases the fibrillation may have been induced by digitalis therapy. With regard to prognosis both groups of investigators agree about the grave outlook in auricular fibrillation in childhood, the subsequent duration of life being less than a year in both groups. Of the cases reported by Stroud, Laplace, and Reisinger, in which the fibrillation was the result of cardiac rheumatism, in 86 per cent. fibrillation began before the age of 40, and in 88 per cent. the patient was dead before the age of 53. In the arteriosclerotic group, however, the incidence was much later, 72 per cent. of the patients not fibrillating until after the age of 53. The duration of life after the onset of fibrillation they find to be roughly the same in the rheumatic and "non-rheumatic" groups, being two and a half years for those patients now dead, and three and a half for those still living; the maximum duration of life after the onset was 16 years in the first group and 14 years in the second. In most of the thyrotoxic cases normal rhythm returned spontaneously after partial thyroidectomy, but in the syphilitic patients with fibrillation the prognosis is bad, the average duration of life being only two years.

Although Stroud and his co-workers have previously reported favourably on the value of quinidine in the treatment of auricular fibrillation, they are now less enthusiastic about it. The patients successfully treated with this drug were specially selected, and had a minimum of detectable myocardial damage, with little or no sign of congestive failure; yet the average duration of life from the onset of fibrillation was in these cases exactly the same as in those which were considered suitable for treatment with quinidine but failed to react, and only little more than a year longer than in those considered unsuitable for this treatment. Moreover, more than half the cases successfully restored to sinus rhythm by quinidine reverted to fibrillation within 12 months. They further find that patients efficiently treated with digitalis are not less comfortable than those in whom normal rhythm has been restored with quinidine, but the latter are anxious and apprehensive lest the fibrillation should return. They therefore conclude that the most beneficial results in auricular fibrillation are obtained with digitalis, and that quinidine should be reserved for a few selected cases in young people with little or no other evidence of cardiovascular abnormality.

◆

GIFT OF AN INFECTIOUS DISEASES HOSPITAL.

For many years past the corporation of Wakefield have had under consideration the provision of a new hospital for infectious diseases, and a few months ago proposals were put forward for its erection at a cost of £71,000, including £4500 for the site. On grounds of economy the scheme was abandoned, and it was decided to spend £5000 on repairing and slightly extending the existing institution. A resident of Wakefield, who makes anonymity a strict condition, has now offered to provide £61,500 for the new hospital, being the entire cost less the £5000 the Council intended to spend, and £4500 the value of the site, already owned by the town. The new hospital, which had been completely planned, will have 89 beds and a theatre. There will be two 24-bed pavilions, a cubicle block of eight beds, a tuberculosis block of 16 beds, a diphtheria pavilion of 17 beds, and the necessary administrative accommodation.

◆

The Milroy lectures of the Royal College of Physicians of London will be delivered on Feb 18th, 23rd, and 25th, by Prof. Cyril Okell, on the Rôle of the Hæmolytic Streptococci in Infective Disease. On March 1st, 3rd, and 8th, Dr. L. J. Witts will give the Goulstonian lectures, on the Pathology and Treatment of Anæmia. Dr. C. E. Lakin's Lumleian lectures will be delivered on March 10th, 15th, and 17th, and their title is the Borderlands of Medicine. Later in the year Miss Harriette Chick, D.Sc., will give the Oliver-Sharpey lectures, on the Relation of Light to Nutrition (May 3rd and 5th), and Dr. J. W. McNee, the Croonian lectures, on the Liver and Spleen and their Clinical and Pathological Associations (June 2nd, 7th, and 9th). All these lectures are to be given at the College at 5 P.M. Members of the medical profession are admitted on presentation of a visiting card.

be asked to decide this question. The Therapeutic Substances Act was framed so carefully as to cover such potentially dangerous material as a living virus, but B C G is not sold like an ordinary vaccine to all who come, but is given away, and the Act does not look such a gift horse in the mouth. As to the third question, the mortality from infantile tuberculosis in this country is high enough to warrant risks, but it is steadily falling. Moreover, in the majority of cases, the disease does not swoop down like a wolf on the fold. B C G has been considered by some an analogous case to calf lymph; but tuberculosis is not like small-pox. There are other remedies, and the outlook is not necessarily black or even grey. These factors have to be reckoned with in deciding whether we shall take risks, and if so how much; the ills we know may be more tolerable than the others that we know not of. And lastly, the risks of infection in tuberculosis persist for some years; if not from childhood to the grave, at least from infancy to manhood. We do not know how long B C G protects, nor whether repeated applications of the vaccine will produce the desired results. Festina lente is not necessarily the counsel of despair; it may be the wisdom of sanity.

◆

VARICELLA AND ZOSTER.

THERE can be little doubt that, were it not for the lack of a suitable experimental animal, the question of the relationship of the viruses of varicella and zoster would have received a definite answer by now. Ever since J. VON BOKAY first put forward the conception of a common ætiology for one type of zoster (zoster varicellosus) and varicella, clinical evidence that zoster gives rise to chicken-pox in susceptible contacts has been steadily accumulating. Some of this evidence, such as that produced by P. J. BRASLAWSKY[1] and P. F. ARMAND DELILLE and Madame TROCMÉ,[2] for instance, has almost the value of a controlled laboratory experiment. And the chain of circumstantial evidence supporting this conception has been considerably strengthened by the serological studies of NETTER and his colleagues; in fact, on the strength of cross complement-fixation reactions, NETTER considers that all cases of zoster, idiopathic and symptomatic, are caused by the virus of varicella. In a recent paper by E. BRUUSGAARD,[3] which starts with a critical and unbiased review of the situation, some experiments on children are described. KUNDRATITZ,[4] he says, reported that young children who had had neither zoster nor varicella, could be infected by dermal inoculation with zoster vesicle fluid, the result being a local vesicular lesion followed, in some instances, by a generalised vesicular eruption indistinguishable from chicken-pox. Children who had had chicken-pox were refractory to the zoster inoculation, and those who had recovered from experimental zoster were not susceptible to the local implantation of chicken-pox vesicle fluid. BRUUSGAARD'S findings are in keeping with those of KUNDRATITZ. Eighteen children were inoculated in the skin with zoster vesicle fluid and eight showed "takes." In four of these there was a local response only, but in the other four there was a generalised eruption indistinguishable from chicken-pox. Further, he was able to transmit the condition by inoculation from one case, and in several instances clinical varicella developed in susceptible children placed in contact with the experimentally infected ones.

Findings such as those of KUNDRATITZ and BRUUSGAARD are very strong evidence that the causal viruses of these two diseases are identical; in fact, it is difficult to see what other interpretation to put on them. Against this conception has been advanced certain epidemiological evidence. Chicken-pox is a disease of childhood, whereas zoster occurs principally in adults. Both diseases apparently confer a lasting immunity, yet it is common for zoster to occur in a person who had varicella in childhood. At first sight these facts are at variance with the idea of a common ætiology for these two diseases, but is this really so? The available evidence suggests that in virus diseases which confer a lasting immunity there is a persistence of the virus in the body; a state of armed neutrality, so to speak. And if this is so, where more likely for the chicken-pox virus to persist than in the central nervous system, where it would be less exposed to the action of viricidal antibody? Later on in adult life, when the immunity acquired from the attack of chicken-pox might be waning, any factor exciting a deleterious action on the central nervous system (trauma, tumours, and poisons such as arsenic and bismuth in symptomatic zoster; unknown in idiopathic zoster) would light the dormant virus into activity giving us the disease zoster. The virus would track to the skin via the spinal nerves, and any subsequent tendency to generalisation would be held in check by the residual chicken-pox immunity. Admittedly this is pure hypothesis, and is not in keeping with the statement that zoster occurs in isolated communities where chicken-pox is unknown—an observation which may not necessarily be correct. But it does help to bring into line conflicting clinical, epidemiological, and experimental evidence, and might conceivably be of service as a working hypothesis in future investigation.

AURICULAR FIBRILLATION.

IN an attempt to throw further light on the cause of this form of cardiac failure, D. MCEACHERN and B. M. BAKER[1] have studied a series of 575 patients with auricular fibrillation seen at the Johns Hopkins Hospital in the past 12 years. Electrocardiographic evidence of the arrhythmia was obtained in all cases. The largest ætiological group was composed of those suffering from rheumatic heart disease, who formed about 34

account rather of the difficulties than of the achievements of the method and from the brief description given it is not easy to appreciate what is likely to be its value. The fuller account which is promised for an early date will therefore be awaited with interest. Meanwhile, the article serves to emphasise rather than to minimise the difficulties of the problem, and one is left still with the impression that, while capacity may be comparatively well assessed by tests, the elusiveness of personality is such that it can only be tested by life.

HYPNOSIS AND ANÆSTHESIA.

It is doubtful whether hypnosis will ever be relied on to play a large part in practical administration of anæsthesia. Indeed Dr. Bernard Hollander disclaimed any pretension of the sort when he read his paper before the anæsthetic section of the Royal Society of Medicine on Feb. 5th. Nevertheless he was able to show from numerous instances in his own experience and that of others that perfect surgical anæsthesia can be obtained purely through hypnosis. He expressed the opinion that in certain circumstances hypnosis should be employed either alone or as an aid to induction, and it appears that it might very well serve sometimes to replace preliminary drugs in procuring calm and banishing apprehension from some types of subject. The paper gave a comprehensive account of the history of hypnosis, but did not venture far into the disputed territory of its physiological and psychological explanations. Nor did subsequent speakers, who included, among others, Lady Berry, Dr. H. Yellowlees, and Dr. J. A. Hadfield, deal much with this side of the subject. A good many personal experiences were related, and one speaker advanced the opinion that, therapeutically, plain speaking on psycho-analytical lines could often effect better than hypnosis and suggestion what the physician was seeking to procure in his patient. Insomnia is certainly a condition for whose relief hypnosis has sometimes succeeded where all else has failed, and the same may be said with reservation of inebriety. For the relief of pain hypnotism can be of great service, and it was interesting to hear Dr. Hollander relate his early experiences in treating patients of the late Sir David Ferrier at King's College Hospital as long ago as the early 'nineties.

BACTERIOPHAGE IN INFANTILE DYSENTERY.

The claims of d'Herelle for the therapeutic value of bacteriophage in bacillary dysentery have received very little support and have been the subject of numerous adverse communications. It has always been a possible objection to negative results that the bacteriophage administered may not have been of maximum potency, but with increasing experience of the properties of this agent the criticism has become of little force. A paper now presented by F. M. Burnet, Margot McKie, and I. J. Wood[1] details the results of this form of treatment in the bacillary dysentery of infants in Australia. This infection is almost wholly of the Flexner type and has been treated by these workers with highly active, polyvalent, anti-Flexner strains of bacteriophage, including d'Herelle's own *Bact-dysenterie-phage*. The results were disappointing, for in 25 treated cases the mortality was 44 per cent., whilst in 33 untreated controls it was 27 per cent. There are certain other facts of interest in these observations. It was noticed that the spontaneous appearance of bacteriophage was relatively rare among the younger infants observed: thus of 19 cases, below the age of 9 months, there were only seven in which the agent was present, whereas of 63 cases over this age, 43 developed a bacteriophage at some period in the course of their illness. This inequality in distribution may perhaps be correlated with the fact that in a detailed analysis of the treated cases the only ones which showed any suggestion of benefit from the specific treatment were the youngest infants. Here, however, the figures given are too small for any conclusions to be drawn. The authors accordingly reach the general conclusion that the Flexner bacteriophage has no influence on the course of infantile dysentery.

MENSTRUATION AND ATHLETICS.

The effect of physical exercise on menstruation has been studied[1] at Kiel, where an athletic sports' meeting in 1930 provided an opportunity for an inquiry amongst the women competitors. A questionaire was prepared beforehand and during the 20 minutes' pauses between the different team events the athletes were introduced in groups and were examined according to the questionaire. In this way 243 competitors were interviewed. The entrants, who were drawn from a large variety of trades and professions, varied in age from 15–39, were divided into two groups: (*a*) those who had joined the athletic club before the onset of puberty; (*b*) those who had joined after puberty. In these two groups there was found to be no marked difference in the age of onset of puberty which was 14·6 years in group (*a*) and 14 years in group (*b*). In answer to inquiry about capacity for work during menstruation the following facts were elicited. Among 243 competitors 7·4 per cent. were better at work or games, 49 per cent. noticed no difference, 35 per cent. found they were less good, and 8 per cent. could not say, for they had never attended physical exercise during a period.

A table was compiled of the irregularities of menstruation remarked in the course of the questionaire and 44 competitors made additional statements. To give the figures and relate the statements in detail is here unnecessary, but they give an important indication of a direct effect of physical exercise on the course of menstruation; further, those cases where a beneficial effect was noted are of definite value as demonstrating clearly that in some cases good does result. The next question to be investigated was "Are disturbances of menstruation found more often or more seldom in athletes than in other women of similar age or profession?" As a control, the statements of girls attending the evening classes in their last year at the Women's Technical School at Kiel were taken; these girls formed a particularly favourable group as scholarships are hard to obtain, and only the healthiest candidates are selected. It was found that disturbances in rhythm of the menstrual period showed similar figures in both classes, but the course of the period showed greater disturbances among members of athletic clubs than among the students. The fact that the loss may be prolonged and increased by physical exercise and that pain may be enhanced if an athletic competition occurs during a period, stood out clearly, though it seemed fair to presume that psychical influences played a part also. From this investigation it appears that there is no necessity to stop all gymnastic

ANNOTATIONS

SCIENCE AND THE MEAT INDUSTRY.

THE indebtedness of the meat industry to science is set out by Dr. T. Moran in the issue of *Chemistry and Industry* for Jan. 29th in an essay which makes useful reading. The transport of meat from the other side of the world to this country, which is the subject of Dr. Moran's reflections, is a triumph of the application of scientific research. Frozen mutton at a temperature in the region of –10° C. is brought to us on a 40-day journey from Australia; the shorter journey from South America, 18 to 25 days, permits of the transport of beef in the chilled state—i.e., at a temperature equal to or slightly below the freezing point of the tissue, roughly –1° C. Owing to its close resemblance to home-killed meat chilled meat as an article of commerce commands a higher price than the same meat when frozen, so that the experiments now being made with the object of bringing mutton in the chilled state from Australia have an economic reason. But on arrival in this country chilled meat, being much more perishable than frozen meat, must be sent to the markets for immediate sale; the vast bulk of frozen meat, on the other hand, is perfectly wholesome after storage for a year or more at –10° C., the growth of micro-organisms ceasing at about –7° C. A certain amount of spoilage occurs owing to oxidation of the fat; lower fatty acids are formed, and, what is more important, aldehydes which impart an unpleasant taste to the fat; bacon suffers especially, and cannot be kept satisfactorily for long periods in cold storage. Investigations made by the Food Investigation Board seem to point to the harmful influence of light. The comparatively short distances between the ports and points of retail in this country make it sufficient for imported chilled and frozen meat to be despatched by road or rail from the docks or markets in insulated vans or containers. For the railway journey from Aberdeen to London, which may afford as an example of the longest journey in Great Britain taken with a commercial objective, a railway van was equipped, as an experiment, with a self-contained refrigerating plant. Methyl chloride was used as the refrigerant; the pump was driven off the axle and the vessel containing the refrigerant was immersed in brine drums containing potassium chromate brine, which has a freezing point of –11·3° C. During stoppages the drums provided a reserve of cold.

Present-day knowledge does not permit of any distinction being made between the actual nutritive value of home-killed, chilled and frozen meat, but there is the all-important question of flavour. The palatability of the flesh is largely dependent upon the breed of the animal. From South America the best quality meat exported is chilled and the lower quality frozen. It is quite possible for imported chilled meat to be superior in flavour to home-killed meat, but to the refined taste the flavour of the best Scotch beef surpasses that of the best chilled beef. Any application of science which makes the appearance of frozen meat approach more closely to that of home-killed meat is appreciated by the meat industry. Frozen meat drips on thawing and the hæmoglobin from the blood is suffused into the neighbouring fat, giving it a pink tinge. It has been found, however, that if the rate of freezing is sufficiently rapid the drip is negligible. This rapid rate can only be realised with small thicknesses of tissue—e.g., steaks and small joints—and then by some special technique, such as freezing in cold brine.

Much is expected from the result of recent investigations on the conditioning or ripening of beef. Meat of inferior quality when kept in cold storage, especially in the form of sides or quarters, increases in palatability and tenderness. This is due to a change in the chemical basis of the connective tissue, collagen, which is readily converted into gelatin. The collagen is present in the form of fine films which ramify in all directions to form a continuous tough membrane; gelatin on the contrary is very tender. When meat is kept in cold storage there is a slow softening and swelling of the collagen.

ASSESSMENT OF TEMPERAMENT.

AN article by Mr. P. E. Vernon in the January number of the *Eugenics Review* is at once a reminder of the weak spot in existing resources for mental testing and a contribution to its strengthening. While general intelligence and specialised aptitudes can now be assessed in such a way as to make estimation of educational and vocational potentialities reasonably accurate "the affective factors of temperament and personality and of interest still seem to be beyond us," and it is these factors which determine whether the potentialities are likely to be realised in actual fact. Mr. Vernon attributes this lack of success in measuring personality to the indefiniteness of temperamental tracts, as compared with qualities of physique and intelligence. One trait may be exhibited by a person in one set of circumstances, and a totally opposite trait by the same person in other circumstances. Different traits may also be elicited in the presence of different observers—teachers, school friends, and relatives may differ greatly in their estimates of a child with regard to a particular trait, or may even describe in differing terms their impressions of a child based upon one and the same episode. All these facts show the unreliability of the rating methods of testing which depend on the judgments of individual observers. Mr. Vernon's own method does not completely evade these difficulties. Stated briefly, it is a method of "sampling" with three parts. To obtain a measure of a person's timidity, for example, a number of test situations are devised to which some would respond with timid, and others with courageous, behaviour, and the reaction of the subject is recorded. The second part is a questionaire about his past behaviour under conditions likely to elicit fear or the opposite. Three or four possible answers being suggested to each question, the subject being asked to supply the answer which best describes himself. The third part is an estimate on a scale by other people, based on actual objective behaviours of his timidity. The samplings have then to be judged and scored in relation to their distribution in a large group of individuals of nearly similar background and age, and when a group of samplings for different traits have been so made and scored for an individual, it is necessary to discover the extent to which the different results correlate. The method is obviously elaborate and liable to fallacy. The reliability, for example, of the subject's replies to the questionaire will depend upon his sincerity in stating his real reaction to the situations presented. The possibilities of bias cannot be excluded from the reports of other observers. Mr. Vernon, indeed, confesses that his paper is an from Brock and Blair's studies is not to allow the recovering heart to pump too forcibly or too much. Early venesection seems definitely demanded to reduce the pressure in the lung, because, as Matzuoka pointed out, œdema could be produced whether the increased pressure was due to a forward or a back pressure, and venesection will lessen both. It seems probable that the condition giving rise to this serious symptom might more often be treated successfully if venesection was carried out promptly.

ARTHUR CHUDLEIGH.

Mr. Arthur Chudleigh, the well-known theatrical manager, who died on Friday, Feb. 5th, had more than one connexion with the medical profession, many members of which, in company with a large public, will regret his death. He was the son of a doctor and, under his real name of Lillies, was educated at Epsom College, the intention being that he should follow his father's career. But an early attraction to the stage dictated for him a very different life. Although as an actor he made no particular mark, he made what was more important, very many friends, through his engaging personal qualities, with the result that he was able when quite a young man and with no private means to take over the management of the Court Theatre. This he did in partnership with Mrs. John Wood, a really popular favourite, and to make an immediate practical success of the venture was the more creditable in that his predecessors in the management, Arthur Cecil and John Clayton, had taught the public to expect much. The high standard of amusement was maintained, and for years the Court Theatre resounded with the laughter due to the wit of the Pinero farces, and their representation by a company of brilliant actors and actresses. This managerial success Chudleigh repeated at the Comedy Theatre, remaining associated with stage production until some 15 years ago. About this time he joined the Council of Epsom College and became an assiduous and generous supporter of the recent developments taking place in the foundation. At the largely attended memorial service, held at St. Martin-in-the-Fields on Tuesday last, the Council of the College and the educational staff were represented.

THE MEDICAL INDUCTION OF LABOUR.

A PAPER by Mr. R. L. Dodds analysing 338 cases of medical induction of labour at the City of London Hospital[1] bears out many conclusions to which we referred in a recent annotation.[2] The cases were studied with a view to evaluation of the factors leading to successful induction and of the risks of repeated attempts as regards the effect both on the course of the subsequent labour and on the fœtus. The method of induction adopted was the administration of 1½ oz. of castor oil followed two hours later by an enema and a hot bath; quinine sulphate, grs. 20, was then given in two-hourly doses of grs. 10, 5, and 5, and, if labour had not begun in 11 hours, two injections of 0·5 c.cm. of pituitrin were given at intervals of an hour. The criterion of success was the onset of labour within 24 hours of the first dose of quinine. Success was obtained in 183 cases (54 per cent.). The usual experience that the degree of maturity is the most potent factor in success was confirmed, the percentages of successful cases being 40, 51, and 65 respectively in 101 cases induced prematurely, 88 induced at term, and 149 induced when the pregnancy had exceeded its usual duration. Albuminuric cases also showed a higher percentage of successes (62) compared with the non-albuminuric (52·7). The chances of success when a second or third course of treatment was tried were less than after the first course, and this lack of sensitiveness of the uterus appeared to show itself also in inertia in the first stage, which was of longer duration, and by a high proportion of instrumental deliveries in the second stage. Too many factors, however, come into consideration—in a group of cases containing a large percentage of inductions performed for disproportion—to allow of definite conclusions. The forceps rate is not as high as in the American figures quoted in our last annotation in which we questioned the advantage of repeated attempts at medical induction because of the very small number of cases in which natural delivery followed. The figures in Mr. Dodds's paper show another experience also noted by the American observer in that no greater success was obtained by the use of grs. 50 of quinine than with grs. 20. The stillbirth-rate was high (10·7 per cent.), and in five cases among 344 births quinine fell under suspicion; but here again so many other complicating factors were present that Mr. Dodds draws the conclusion that less than 2 per cent. of medically induced labours result in stillbirths "possibly due to quinine."

THE IRIS IN VERTEBRATES.

THE latest fruit of Miss Ida Mann's research into the comparative anatomy of the eye is an elaborate account of the iris in vertebrates.[1] It is enriched by 57 coloured illustrations, most of them pictures of the irides of animals in the Zoological Gardens, London, and in themselves very beautiful. These pictures had to be made from the living eye, and while reptiles and amphibians proved fairly amenable, the mammals were usually troublesome and the fish very difficult. The characters to which special attention was directed were arrangement of blood-vessels, shape of pupil, nature and distribution of pigment, and relation of pigment pattern to skin pattern where such existed. In mammals the main plan of the circulation never varies; there is a circumferential arterial circle giving radial branches superficially to the inner circle where they anastomose with veins. The human iris is typical. The shape of the pupil, however, is very variable in mammals, deviations from the circular shape being correlated with the mode of life of the animal. In nocturnal animals, including most carnivores, it is vertically oval. In diurnal, shade-loving animals such as herbivores it is oval horizontally. As to pigmentation, in mammals this is typically some shade of brown. All the varieties of colour in the human iris are due to varying amounts and distribution of this pigment, most of it deposited as a rule during the first six months after birth. In birds, the vascular arrangement, which is to be considered the most fundamental character, is different from that seen in mammals. There being no pupillary membrane the superficial layer of the iris is absent, and the vessels correspond to those in the deeper layer of the mammalian iris, which are not normally visible during life. The sphincter of the pupil is well developed and is composed of striped muscle, not contracting reflexly to light exercises during a menstrual period, for sometimes disturbances of menstruation were found to disappear when physical exercises were continued during the period. On the other hand, there appeared to be a certain number of women whose constitution required that they should spare themselves during menstruation and these should not be induced to continue physical exercise at that time.

HEAT-STROKE.

HEAT-STROKE has received more notice lately, and a recent number of the *Tropical Diseases Bulletin*[1] summarises eight papers which have appeared during the past year. P. Cazamian,[2] it is stated, gives a careful study of heat-stroke as it is seen in steamships and takes the view that coagulation of myosin occurs in the affected muscles. He recommends injections of ether, caffeine, camphor, and glucose, and plenty of fluid to drink. Twenty mild cases among the troops in Allahabad have been described by C. F. P. Hamilton, D. N. Busu, and J. Van Haeften,[3] and F. Marsh has discussed the ætiology[4] and described experiments with rabbits, from which he concludes that the heat rays and not the ultraviolet rays are responsible for heat-stroke. Since these contributions were analysed in the bulletin Surgeon-Lieut. Hugh Willoughby and Flight-Lieut. Edward Aslett[5] have produced a review of the subject which repays attention.

The term "heat-stroke" they point out, does not represent a simple clinical entity but includes three morbid states—heat exhaustion, heat hyperpyrexia, and sun traumatism. Heat exhaustion is a syncope with symptoms of shock, directly due to interference with heat loss. The attack is generally sudden and short, characterised by giddiness, collapse, dilated pupils, cold skin, soft, small fluttering pulse, and subnormal temperature. The patient usually recovers when placed in a cool temperature and given stimulants. As his temperature is already subnormal he should not be douched, but his face may be sprayed with cold water, and in severe cases camphor in oil may be injected and hot-water bottles applied. These writers recommend brandy as an excellent standby. A man ought to be ready for duty again in 24 to 48 hours. Heat hyperpyrexia is due to exposure to high temperature, but occurs in certain districts only: in the valleys and deltas of rivers and on low-lying coasts, but never on the high seas. It is due to inability to lose heat by the normal routes. It may be predominantly nervous, gastric, or choleraic in its symptomatology. The temperature may be as high as 110° F., the face is flushed, the skin hot and dry, the breathing stertorous, and consciousness entirely lost. The pupils are contracted, and the urine, which is usually offensive, contains indican. Prompt and energetic treatment is essential; the temperature must be reduced to 104° F. by sprays, douches, and iced enemata, and then the patient should be wrapped in a dry blanket and left alone lest hypopyrexia follow. In a dry climate the temperature is best reduced by a fine spray, covering the body with small globules to dissipate heat by evaporation; in humid climates heavy douching with iced water and rubbing the body with ice, to dissipate heat by conduction, is better. Alcohol is contra-indicated until sweating is re-established, and strychnine must never be given. Artificial respiration may be necessary, and strophanthin and intravenous alkali are useful. An attack can be prevented by proper attention to premonitory symptoms: restlessness, vertigo, headache, confusion, anorexia, thirst, sighing, nausea, vomiting, and suppression of sweat. In Willoughby and Aslett's opinion, nobody who has had an attack of heat hyperpyrexia should continue to live in the tropics.

The third form of heat-stroke—sun traumatism—they ascribe to some unexplained action of the heat rays of the sun, but an attack often occurs on an overcast day. The symptoms are intense headache and intolerance to light and sound, rapid full pulse, vomiting, dry skin, and perhaps delirium. The treatment consists in absolute rest and quiet in a dark room, with ice packs for the head and bromides if necessary. The after-effects may be serious—loss of memory, mental confusion, and inability to concentrate—and here again the patient should cease to live in the tropics.

This useful review by Willoughby and Aslett includes a comparative table of the three conditions and some remarks on their differential diagnosis from other states, notably cerebral malaria, which should never be overlooked in tropical practice. They recommend the establishment of a "heat-stroke station" at sick quarters and suggest the form which this should take. The heat-stroke ward in the hospital of the Anglo-Persian Oil Co. at Masjid-i-Suleiman has been described by Frank Marsh[4] and also by D. C. Rennie.[6] Its cost amounts to between £400 and £500 per annum and no case has gone on to heat-stroke since the ward was opened.

ACUTE PULMONARY ŒDEMA.

ACUTE pulmonary œdema is one of the most dramatic symptoms in medicine, and several theories have been advanced to explain its origin. Cases in which it develops after the exhibition of various drugs such as organic arsenical preparations or quinine, after exposure to irritating gases, or as a manifestation of some chemical poison, form but a small though clear group compared with those in which it occurs in the course of heart disease, especially mitral stenosis or hypertensive heart failure, whether due to renal disease or hyperpiesia. A paper by R. C. Brock and E. A. Blair[7] dealing with experiments on respiratory movements, describes in detail the series of events in the production of the œdema and in a few particulars amplifies the work done on that subject by Y. Matzuoka in 1915. In the heart-lung preparation they found that occasionally for some obscure reason, when the artificial circulation was opened up, the heart failed to maintain an efficient circulation. As the cardiac condition improved, this failure was almost always followed by a rapidly progressive pulmonary œdema. This is what the clinician would expect from observations on human beings, and it gives clear indications and contra-indications for treatment. As M. C. Winternitz and R. A. Lambert pointed out in 1919, it is not the œdema that kills but the underlying serious state, and it is not surprising that atropine is useless. Brock and Blair also observed in their experiments that respiratory movements increased the œdema and consequently the use of artificial respiration as advised by H. Emerson in 1909 and based on animal experiments seems unjustifiable. But the definite indication gained from Brock and Blair's studies is not to allow the recovering heart to pump too forcibly or too much. Early venesection seems definitely demanded to reduce the pressure in the lung, because, as Matzuoka pointed out, œdema could be produced whether the increased pressure was due to a forward or a back pressure, and venesection will lessen both. It seems probable that the condition giving rise to this serious symptom might more often be treated successfully if venesection was carried out promptly.

ARTHUR CHUDLEIGH.

Mr. Arthur Chudleigh, the well-known theatrical manager, who died on Friday, Feb. 5th, had more than one connexion with the medical profession, many members of which, in company with a large public, will regret his death. He was the son of a doctor and, under his real name of Lillies, was educated at Epsom College, the intention being that he should follow his father's career. But an early attraction to the stage dictated for him a very different life. Although as an actor he made no particular mark, he made what was more important, very many friends, through his engaging personal qualities, with the result that he was able when quite a young man and with no private means to take over the management of the Court Theatre. This he did in partnership with Mrs. John Wood, a really popular favourite, and to make an immediate practical success of the venture was the more creditable in that his predecessors in the management, Arthur Cecil and John Clayton, had taught the public to expect much. The high standard of amusement was maintained, and for years the Court Theatre resounded with the laughter due to the wit of the Pinero farces, and their representation by a company of brilliant actors and actresses. This managerial success Chudleigh repeated at the Comedy Theatre, remaining associated with stage production until some 15 years ago. About this time he joined the Council of Epsom College and became an assiduous and generous supporter of the recent developments taking place in the foundation. At the largely attended memorial service, held at St. Martin-in-the-Fields on Tuesday last, the Council of the College and the educational staff were represented.

THE MEDICAL INDUCTION OF LABOUR.

A PAPER by Mr. R. L. Dodds analysing 338 cases of medical induction of labour at the City of London Hospital[1] bears out many conclusions to which we referred in a recent annotation.[2] The cases were studied with a view to evaluation of the factors leading to successful induction and of the risks of repeated attempts as regards the effect both on the course of the subsequent labour and on the fœtus. The method of induction adopted was the administration of 1½ oz. of castor oil followed two hours later by an enema and a hot bath; quinine sulphate, grs. 20, was then given in two-hourly doses of grs. 10, 5, and 5, and, if labour had not begun in 11 hours, two injections of 0·5 c.cm. of pituitrin were given at intervals of an hour. The criterion of success was the onset of labour within 24 hours of the first dose of quinine. Success was obtained in 183 cases (54 per cent.). The usual experience that the degree of maturity is the most potent factor in success was confirmed, the percentages of successful cases being 40, 51, and 65 respectively in 101 cases induced prematurely, 88 induced at term, and 149 induced when the pregnancy had exceeded its usual duration. Albuminuric cases also showed a higher percentage of successes (62) compared with the non-albuminuric (52·7). The chances of success when a second or third course of treatment was tried were less than after the first course, and this lack of sensitiveness of the uterus appeared to show itself also in inertia in the first stage, which was of longer duration, and by a high proportion of instrumental deliveries in the second stage. Too many factors, however, come into consideration—in a group of cases containing a large percentage of inductions performed for disproportion—to allow of definite conclusions. The forceps rate is not as high as in the American figures quoted in our last annotation in which we questioned the advantage of repeated attempts at medical induction because of the very small number of cases in which natural delivery followed. The figures in Mr. Dodds's paper show another experience also noted by the American observer in that no greater success was obtained by the use of grs. 50 of quinine than with grs. 20. The stillbirth-rate was high (10·7 per cent.), and in five cases among 344 births quinine fell under suspicion; but here again so many other complicating factors were present that Mr. Dodds draws the conclusion that less than 2 per cent. of medically induced labours result in stillbirths "possibly due to quinine."

THE IRIS IN VERTEBRATES.

THE latest fruit of Miss Ida Mann's research into the comparative anatomy of the eye is an elaborate account of the iris in vertebrates.[1] It is enriched by 57 coloured illustrations, most of them pictures of the irides of animals in the Zoological Gardens, London, and in themselves very beautiful. These pictures had to be made from the living eye, and while reptiles and amphibians proved fairly amenable, the mammals were usually troublesome and the fish very difficult. The characters to which special attention was directed were arrangement of bloodvessels, shape of pupil, nature and distribution of pigment, and relation of pigment pattern to skin pattern where such existed. In mammals the main plan of the circulation never varies; there is a circumferential arterial circle giving radial branches superficially to the inner circle where they anastomose with veins. The human iris is typical. The shape of the pupil, however, is very variable in mammals, deviations from the circular shape being correlated with the mode of life of the animal. In nocturnal animals, including most carnivores, it is vertically oval. In diurnal, shade-loving animals such as herbivores it is oval horizontally. As to pigmentation, in mammals this is typically some shade of brown. All the varieties of colour in the human iris are due to varying amounts and distribution of this pigment, most of it deposited as a rule during the first six months after birth. In birds, the vascular arrangement, which is to be considered the most fundamental character, is different from that seen in mammals. There being no pupillary membrane the superficial layer of the iris is absent, and the vessels correspond to those in the deeper layer of the mammalian iris, which are not normally visible during life. The sphincter of the pupil is well developed and is composed of striped muscle, not contracting reflexly to light exercises during a menstrual period, for sometimes disturbances of menstruation were found to disappear when physical exercises were continued during the period. On the other hand, there appeared to be a certain number of women whose constitution required that they should spare themselves during menstruation and these should not be induced to continue physical exercise at that time.

HEAT-STROKE.

HEAT-STROKE has received more notice lately, and a recent number of the *Tropical Diseases Bulletin*[1] summarises eight papers which have appeared during the past year. P. Cazamian,[2] it is stated, gives a careful study of heat-stroke as it is seen in steamships and takes the view that coagulation of myosin occurs in the affected muscles. He recommends injections of ether, caffeine, camphor, and glucose, and plenty of fluid to drink. Twenty mild cases among the troops in Allahabad have been described by C. F. P. Hamilton, D. N. Busu, and J. Van Haeften,[3] and F. Marsh has discussed the ætiology[4] and described experiments with rabbits, from which he concludes that the heat rays and not the ultraviolet rays are responsible for heat-stroke. Since these contributions were analysed in the bulletin Surgeon-Lieut. Hugh Willoughby and Flight-Lieut. Edward Aslett[5] have produced a review of the subject which repays attention.

The term "heat-stroke" they point out, does not represent a simple clinical entity but includes three morbid states—heat exhaustion, heat hyperpyrexia, and sun traumatism. Heat exhaustion is a syncope with symptoms of shock, directly due to interference with heat loss. The attack is generally sudden and short, characterised by giddiness, collapse, dilated pupils, cold skin, soft, small fluttering pulse, and subnormal temperature. The patient usually recovers when placed in a cool temperature and given stimulants. As his temperature is already subnormal he *should not be douched, but his face may be sprayed* with cold water, and in severe cases camphor in oil may be injected and hot-water bottles applied. These writers recommend brandy as an excellent standby. A man ought to be ready for duty again in 24 to 48 hours. Heat hyperpyrexia is due to exposure to high temperature, but occurs in certain districts only: in the valleys and deltas of rivers and on low-lying coasts, but never on the high seas. It is due to inability to lose heat by the normal routes. It may be predominantly nervous, gastric, or choleraic in its symptomatology. The temperature may be as high as 110° F., the face is flushed, the skin hot and dry, the breathing stertorous, and consciousness entirely lost. The pupils are contracted, and the urine, which is usually offensive, contains indican. Prompt and energetic treatment is essential; the temperature must be reduced to 104° F. by sprays, douches, and iced enemata, and then the patient should be wrapped in a dry blanket and left alone lest hypopyrexia follow. In a dry climate the temperature is best reduced by a fine spray, covering the body with small globules to dissipate heat by evaporation; in humid climates heavy douching with iced water and rubbing the body with ice, to dissipate heat by conduction, is better. Alcohol is contra-indicated until sweating is re-established, and strychnine must never be given. Artificial respiration may be necessary, and strophanthin and intravenous alkali are useful. An attack can be prevented by proper attention to premonitory symptoms: restlessness, vertigo, headache, confusion, anorexia, thirst, sighing, nausea, vomiting, and suppression of sweat. In Willoughby and Aslett's opinion, nobody who has had an attack of heat hyperpyrexia should continue to live in the tropics.

The third form of heat-stroke—sun traumatism—they ascribe to some unexplained action of the heat rays of the sun, but an attack often occurs on an overcast day. The symptoms are intense headache and intolerance to light and sound, rapid full pulse, vomiting, dry skin, and perhaps delirium. The treatment consists in absolute rest and quiet in a dark room, with ice packs for the head and bromides if necessary. The after-effects may be serious—loss of memory, mental confusion, and inability to concentrate—and here again the patient should cease to live in the tropics.

This useful review by Willoughby and Aslett includes a comparative table of the three conditions and some remarks on their differential diagnosis from other states, notably cerebral malaria, which should never be overlooked in tropical practice. They recommend the establishment of a "heat-stroke station" at sick quarters and suggest the form which this should take. The heat-stroke ward in the hospital of the Anglo-Persian Oil Co. at Masjid-i-Suleiman has been described by Frank Marsh[4] and also by D. C. Rennie.[6] Its cost amounts to between £400 and £500 per annum and no case has gone on to heat-stroke since the ward was opened.

ACUTE PULMONARY ŒDEMA.

ACUTE pulmonary œdema is one of the most dramatic symptoms in medicine, and several theories have been advanced to explain its origin. Cases in which it develops after the exhibition of various drugs such as organic arsenical preparations or quinine, after exposure to irritating gases, or as a manifestation of some chemical poison, form but a small though clear group compared with those in which it occurs in the course of heart disease, especially mitral stenosis or hypertensive heart failure, whether due to renal disease or hyperpiesia. A paper by R. C. Brock and E. A. Blair[7] dealing with experiments on respiratory movements, describes in detail the series of events in the production of the œdema and in a few particulars amplifies the work done on that subject by Y. Matzuoka in 1915. In the heart-lung preparation they found that occasionally for some obscure reason, when the artificial circulation was opened up, the heart failed to maintain an efficient circulation. As the cardiac condition improved, this failure was almost always followed by a rapidly progressive pulmonary œdema. This is what the clinician would expect from observations on human beings, and it gives clear indications and contra-indications for treatment. As M. C. Winternitz and R. A. Lambert pointed out in 1919, it is not the œdema that kills but the underlying serious state, and it is not surprising that atropine is useless. Brock and Blair also observed in their experiments that respiratory movements increased the œdema and consequently the use of artificial respiration as advised by H. Emerson in 1909 and based on animal experiments seems unjustifiable. But the definite indication gained

SPECIAL ARTICLES

A STUDY OF THE B C G STRAIN OF TUBERCLE BACILLUS.

WITH AN ACCOUNT OF TWO IMMUNITY EXPERIMENTS AND A PRELIMINARY REPORT ON THE CULTIVATION OF TUBERCLE BACILLI ON BILE MEDIA.

By A. Stanley Griffith, M.D. Vict.,
Ph.D. Camb.,
MEMBER OF THE SCIENTIFIC STAFF, MEDICAL RESEARCH COUNCIL.

(From the Field Laboratories, University of Cambridge.)

(Concluded from p. 305.)

The Two Immunity Experiments.

The immunity experiments reported in The Lancet by Buxton and Griffith[6] showed that a high degree of resistance against experimental tuberculosis can be conferred upon calves by vaccination with B C G. In that paper mention was made of two preliminary immunity experiments on calves, the details of which were not then given. Advantage is taken of this report to put them on record.

The experiments were undertaken by me in 1926 for the purpose of comparing the immunising value of B C G with that of an attenuated though still nosogenic strain of human tubercle bacilli obtained from lupus.

The calves which were kindly presented to me by Prof. J. B. Buxton were 3 to 4 months old and had not reacted to the double intradermal tuberculin test.

The following table gives the details of the vaccinations.

Date in 1926.	Method of vaccination.	Calf B. B C G.	Calf C. H 131 (lupus).
Jan. 28th ..	Subcut.	100 mg.	100 mg.
March 17th ..	Intrav.	5 ,,	5 ,,
May 5th ..	,,	10 ,,	10 ,,
June 21st ..	,,	50 ,,	50 ,,

Both calves reacted on May 5th to the intravenous injection of the third dose of vaccine, the temperature rising to 104·5° F. and 105·2° F. respectively.

Resistance test.—On August 26th, 1926, 66 days after the last dose of vaccine each calf was inoculated intravenously with 1·0 mg. of virulent bovine tubercle bacilli. At the same time two adult goats, one 18 months and one some years old, were inoculated intravenously with ·01 mg. of the same bovine culture to serve as controls, no calves being available. The goats died in 35 and 38 days of severe miliary tuberculosis of the lungs, the thoracic glands also showing extensive tuberculosis. Both calves reacted vigorously to the test inoculation and were ill for about a week; the temperatures rose to 106·8° F. and 107·3° F. respectively at the 21st hour and remained at a high level for three days, after which they fell to normal. The calves regained their health and grew into fine beasts.

The bullock (calf C) was used towards the end of 1927 for the purpose of producing a therapeutic serum and was given a series of injections of B C G. On Sept. 16th, 1927, he was injected subcutaneously with 200 mg. of B C G; there was no temperature reaction. On Oct. 3rd, 1927 he was given an intravenous inoculation of 10 mg. B C G; the temperature rose 3·1° F. at the 15th hour, and was high for three days. On Nov. 17th, 1927, an intravenous inoculation of 10 mg. of B C G again gave a good reaction. On Dec. 7th, 1927, a dose of 100 mg. of B C G was inoculated intravenously; the temperature rose on this occasion from 101·4° F. just before the injection to 105·8° F. at the 16th hour and 105·9° F. at the 19th hour, and was maintained at a high level during three days. On May 20th, 1928, five and a half months after the last dose of B C G, the double intradermal tuberculin test gave a negative reaction.

The bullock was killed on May 23rd, 1928, 1 year 270 days after the resistance test. The autopsy showed no sign of tuberculosis and guinea-pigs inoculated with emulsions of the thoracic, mesenteric and prescapular glands did not become tuberculous.

The heifer (Calf B) was sent to the bull on Sept. 16th, 1927; she was then in excellent health and condition. On June 27th, 1928, she gave birth to a healthy calf which was brought up on the mother's milk. Two months later the calf did not react to the double intradermal test or to an intravenous injection of 10 mg. of B C G and was used for an immunity experiment (see calf D, The Lancet, 1931, i., 393).

Two months before full term some mammary secretion from each of the four quarters of the udder of the heifer was withdrawn and tested for the presence of tubercle bacilli. No colonies of tubercle bacilli were obtained on culture tubes and a guinea-pig inoculated with the secretion remained healthy.

Before calving the heifer became weak in the hind limbs; the weakness, I thought, was traumatic and caused by the bullock who lived in the same paddock. After calving she became weaker, and on August 20th, 1928, i.e., two years after the test dose, she was slaughtered. At the autopsy no sign of tuberculosis was found anywhere.

There is, of course, nothing new in the production of immunity in cattle against tuberculosis by the inoculation of living tubercle bacilli. The experiments of numerous observers have shown that by the inoculation of living cultures of human, avian, or—in small doses—bovine tubercle bacilli, or of attenuated strains of any of these three types, the specific resistance of a bovine animal can be raised sufficiently to protect it against the inoculation of a dose of bovine bacilli which is capable of setting up severe and fatal tuberculosis in an animal not so protected.

The use of living tubercle bacilli which have some pathogenicity is, however, inadmissible, since it has been shown that the bacilli may be excreted in the milk, or may remain alive for long periods in the tissues or, in the case of attenuated strains, may regain their virulence,[8] [9] and thus be the means of propagating tuberculosis from cattle to man.

B C G is an attenuated strain of the tubercle bacillus, but it is claimed by the originators that this strain is incapable of causing progressive tuberculosis in man or any species of animal or of regaining its original virulence during long stay in the human or the animal body. This claim is supported by the results of the researches of the majority of tuberculosis workers.

On the other hand, a few investigators are not in agreement with the view that B C G may be regarded as certainly free from all danger to man and animals. For example, Watson and his collaborators,[15] and Uhlenhuth and Seiffert[16] believe that B C G has sometimes produced progressive tuberculosis in guinea-pigs. Petroff, Branch and Steenken[3] claim to have dissociated a virulent element from an original culture. Dreyer and Vollum[17] believe that the culture may acquire virulence when grown in the depth of broth. Sasano and Medlar[18] report that they have obtained a virulent strain by growing B C G on the surface of broth. Komis[19] thinks he has succeeded in rendering B C G virulent by means of fermentation with wine yeast.

Attempts to Attenuate Tubercle Bacilli by Growing them on Bile Media.

In their first paper on the subject Calmette and Guérin[20] make the interesting statement that the bovine strain, eventually to be named B C G, after a single subculture on bile potato exhibited a little higher virulence for the guinea-pig than the same strain of bacilli which had been maintained on ordinary potato. Guinea-pigs inoculated intraperitoneally with 1·0 mg. of the bile bacilli always died within 18 days as in the mammal, but apparently under voluntary control. Most of the visible vessels are part of a large capillary plexus covering the sphincter on a background of pigment which is of very various colours in different species. Reptiles and amphibia exhibit their own peculiarities; metallic pigment is often present and there is a protective colour-striping of the whole head involving the lids, conjunctiva, and iris stroma. This is especially well seen in snakes. In frogs the shape of the pupil has different outlines according to the particular species, and in many species the shape alters with the illumination—for instance, from pear-shaped to heart-shaped, dilating to a complete circle in very dim light. In fish there is a remarkable brilliance of coloration and many fish, such as the salmon, have a notch on the inner side of the pupil, not a true coloboma, but displaying an aphakic area such as in human beings is seen in cases of dislocated lens.

There are many other peculiar varieties in the vertebrate iris which may be studied in this fascinating work. One is seen in the gecko, a specialised form of lizard. These animals are nocturnal hunters, but in the day sit basking on tree trunks in full sunlight. In dull light the pupil dilates widely to a complete circle. In bright sunlight it narrows to a long vertical line and appears to be completely closed. On careful examination, however, four small diamond-shaped openings in the slit can be discovered. These allow good vision in daylight without dazzle and with a wide vertical field of vision. With a normal lens the four rays of light would all be focused on the same point in the retina, so that single vision would result.

WEATHER CHANGES AND HEALTH.

We hope that the new Section of Physical Medicine of the Royal Society of Medicine will be stimulated rather than depressed by the chilly agnosticism which the director of the Meteorological Office brought to its first meeting.[1] Dr. Simpson maintained that the only important influence which weather had on the body is its extraction of heat. In most rooms in this country, he said, enough air exchange is effected to obviate any ill-effects, and those of us who become depressed when the windows are closed must consider our symptoms "chiefly psychological." In a letter this week Fleet-Surgeon W. E. Home welcomes this point of view as preferable to the old and discouraging idea that tropical diseases were due to climate. At the same time he records interesting observations about the relation between air humidity and illness, and it seems a pity that curiosity on such points should be rare, except, apparently, among members of the Home family. Close investigation might reveal more justification for the layman's steady belief in a connexion between bodily and climatic changes. It has been noticed, for instance, that colds and chills more commonly follow a change towards warmer than towards cooler weather, and Dr. K. Stotle,[2] of Breslau, has lately tried—though not with much success—to explain this paradox in the medical language of our time. In the first place he records how children who have remained healthy throughout the winter contract tonsillitis or nasopharyngitis with the first warm days of spring although there is no reason to suppose they have been chilled. He further points out how common it is for town children sent to convalescent homes in the country to develop coughs and colds within a few days of arrival, although their surroundings are much improved. Again, he says, it is well known that tuberculous meningitis grows commoner in spring. The increase does not occur at any constant month, and has nothing to do with poor nourishment and bad surroundings during the winter, for it is seen in all classes. While usually appearing from the middle of February to the middle of April this increase of acute tuberculous affections in childhood was delayed in 1931 until May, owing to an exceptionally long winter. In other words, it is the first warm days of spring which appear to be the climatic factor rather than the lack of sun during the winter months. Seeking for some explanation of these observations Stotle points out that in children the maximum period of growth takes place during spring, and he thinks that in this increase in new cells lies the possibility of decreased resistance to disease. Further, he remarks that ultra-violet radiation produces definite alterations in the mineral content of the blood—as shown in its extreme form in rickets—and such biochemical changes, especially as they affect the water content of the tissues, may well be associated with alterations in resistance to infection.

Mr. Wilfred Trotter, F.R.S., will deliver the Hunterian Oration before the Royal College of Surgeons of England at 4 P.M. on Monday, Feb. 15th. His subject is the Commemoration of Great Men.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. J. D. Murphy is placed on the retd. list.

The following appointments are notified: Surg. Lt.-Cmdrs. R. W. Mussen to *President* for Naval Medical School, Greenwich; and E. R. Sorley to *Malabar* for Bermuda Hospital.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Sub.-Lt. J. D. Spillane to be Surg. Sub-Lt.

Proby. Surg. Lt. (D). E. N. F. Jenkins to *Victory* for Haslar Hospital.

ROYAL ARMY MEDICAL CORPS.

Maj. W. J. F. Craig, from the secd. list, is restd. to the estabt.

Lt. (prov. Capt.) J. W. Kendall half-pay list, relinquishes the prov. rank of Capt.

D. P. F. Mulvany from a temp. commn. to be Lt.

TERRITORIAL ARMY.

Lts. H. A. Bulman, A. Roberts, and F. Lawence to be Capts.

ROYAL AIR FORCE.

Medical Branch.—The undermentioned are granted short service commissions as Flying Officers for three years on the active list: F. W. P. Dixon, C. R. Palfreyman, J. A. Kersley, D. C. MacGilchrist, C. A. Rumball, and A. M. Weston.

Flight Lt. A. S. Burns is granted a permanent commission in this rank.

Squadron Leader H. B. Troup is placed on the retd. list on account of ill-health.

INDIAN MEDICAL SERVICE.

Capt. (prov.) C. K. Lakshmanan is confirmed in his rank.

Lt. J. F. Shepherd to be Capt.

DEATHS IN THE SERVICES.

Lt.-Col. Samuel Forster Lougheed, C.M.G., R.A.M.C.; retd., who died on Feb. 4th at the age of 72 was the son of the late S. Lougheed, of Ballinakill, Co. Sligo, Graduating M.D., R.M.I., in 1881, he entered the Army in the following year and served throughout the South African War from 1889 to 1902 (mentioned in despatches, Queen's Medal with three clasps and the King's Medal with two clasps). He received the C.M.G. in 1900.

His wife, who pre-deceased him in 1920, was the daughter of the late C. Hammerton, of Horsham.

---

[1] See The Lancet, Jan. 30th, p. 242.

[2] Jahrb. f. Kinderheilk., 1931, cxxxiv., 6.

inoculation or in the adjacent glands; the anterior lobes of the lungs, however, each contained a caseous mass, that in the right being the more advanced; the bronchial glands, particularly the right, were much enlarged and caseating; the spleen contained caseating nodules and the liver grey tubercles. A highly dysgonic culture was obtained from the bronchial glands.

These two guinea-pigs had been put, through a misinterpretation of instructions, in a house containing guinea-pigs infected with mammalian tubercle bacilli.

3. A guinea-pig, one of another pair which had been inoculated with deep broth cultures of B C G. The cultures were seven months old (little if any multiplication had occurred) and the growth from one flask was injected intraperitoneally into each guinea-pig.

One guinea-pig was killed 82 days later and showed a pea-sized abscess in the omentum from which B C G was not recovered in culture. The other died of pleural effusion in 79 days. The omentum and the mesenteries were thickened and contracted and adherent to surrounding structures, the omentum containing an abscess; there were numerous small yellowish-white caseous masses on the visceral peritoneum, many loosely attached by fine fibrous strands: there was deposit of a similar nature between the liver and the diaphragm. The sternal and manubrial glands were a little enlarged and opaque. There were no tuberculous lesions in the spleen, liver or lungs. The mid-cervical gland on the right side was enlarged and composed throughout of firm creamy caseous substance: no other gland was affected in this way. Microscopically the caseous substance from the abdomen showed numerous beaded tubercle bacilli. Numerous egg and glycerin egg tubes sown from abdominal pus, the sternal and manubrial glands remained sterile. An emulsion of sternal gland did not produce tuberculosis in a guinea-pig.

A culture of tubercle bacilli was obtained from the cervical gland. The culture was dysgonic, though not highly so. Two guinea-pigs were inoculated subcutaneously, each with 1·0 mg. of the culture. One killed 101 days later showed general tuberculosis of a mild type. The other died in 150 days of severe chronic general tuberculosis. These guinea-pigs lived longer than is usual for guinea-pigs inoculated with 1·0 mg. of fully virulent bovine bacilli. A rabbit inoculated intravenously with 0·01 mg. of the culture died in 33 days of severe general miliary tuberculosis.

MEDICINE AND THE LAW.

Hospital Benefits by Subscription.

THE Assurance Companies Act of 1909, in this respect superseding an older enactment of 1870, requires that persons or bodies carrying on life insurance in the United Kingdom must deposit in court a sum of £20,000, to be invested in approved securities. The obvious purpose of this requirement is to make sure that such undertakings are solid, solvent, and permanent, so that anyone who thriftily pays his premiums year after year shall not find his security suddenly vanish when he most needs it. The question has lately arisen whether the British Provident Association for Hospital and Additional Services is within the statute, and is therefore obliged to make the £20,000 deposit. The Association was formed in 1923 to recoup to its subscribers their expenses in hospitals and nursing homes or in respect of surgical operations. It has no share capital; it is a company "not for profit." Its articles of association allow no dividend or bonus to be paid to members; in the event of its dissolution, surplus funds are to go to charitable purposes. Its prospectus invited subscriptions and described the financial help which subscribers would receive towards the expenses already described and the limits of amount and duration. Every subscriber received a card explaining the amounts due from him; it warned him that the amount of benefit depended on the amount subscribed and on the calls for contributions made on the Association. Subscribers were given no policy of insurance; indeed the memorandum of association expressly provided that the Association was not to conduct insurance business.

A friendly test action was brought before Mr. Justice Farwell, who has held that the Association is carrying on a charitable business, is not issuing insurance policies, and is outside the statutory requirement as to depositing £20,000. He did not regard the combined effect of prospectus and subscription as a policy; it was merely a contract to pay benefits according to the undertakings in the prospectus. The operations of the Association therefore are neither illegal owing to the omission to deposit £20,000, nor ultra vires owing to breach of the provision in the memorandum which stipulates that the Association shall not conduct insurance business.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

AMALGAMATION OF HOSPITALS IN DUBLIN.

THE Charter Day dinner of the Royal College of Surgeons in Ireland was held in the College Hall last Saturday, with Mr. Richard Atkinson Stoney, the President, presiding. There was a large number of guests, the principal being Mr. James McNeill, Governor General of the Irish Free State. The President in his speech dealt with the question of amalgamation of the Dublin hospitals in a rather critical spirit. As Mr. Stoney has hitherto been a supporter of the project of amalgamation his present views are likely to attract attention. It is true that he warned his hearers against the assumption that he was necessarily opposed to amalgamation in any form, but there was danger that in grasping at a shadow the Dublin hospitals might lose many real advantages which were inherent in their present system. Moreover, the expense of building and equipping an amalgamated hospital of sufficient size to be worth while would require—at a rate of £1000 a bed—from half a million to a million pounds, and the scrapping of the present hospitals would be a very wasteful procedure. He went on to direct attention to certain advantages of the present system, which he thought would be lost if the hospitals were amalgamated into one or two large hospitals. First he placed the custom existent in Dublin of receiving medical students as "resident students" in the hospitals, thereby accustoming them, before qualification, to dealing with patients with a certain degree of responsibility. He regarded the rivalry between a number of small teaching hospitals as healthy in that it stimulated the teachers to make sure that their teaching was of the best if they were to attract students and keep up a good class. Again, by the system of small hospitals the clinical classes were kept comparatively small so that the student could receive individual attention and teaching. From the point of view of the patients, it was of advantage to have the hospitals scattered widely over the city so that they were easy of access.

Mr. Stoney, however, gave no reason for his view while guinea-pigs inoculated with the same dose of the same strain on potato survived for periods of from 20 to 45 days.

Two tests were made by me with the Pasteur Institute strain of bovine bacilli, named "Bovine Vallée," on media with and without bile.

Experiment 1 (July, 1931).—Two guinea-pigs were inoculated intraperitoneally with 1·0 mg. of the strain grown for 35 days on a 5 per cent. glycerin bile egg tube. At the same time two guinea-pigs were similarly inoculated with a 35 day old culture of the strain on plain egg. The guinea-pigs inoculated with the bile culture died of subacute general tuberculosis in 36 and 42 days. The guinea-pigs inoculated with the plain egg culture died of acute tuberculosis in 12 and 19 days.

Experiment 2 (September, 1931).—As above with the exception that the cultures used were 28 days old. The guinea-pigs inoculated with the bile culture died of general tuberculosis in 23 and 21 days while those inoculated with the plain egg culture died in 19 and 26 days, one of acute, the other of subacute general tuberculosis.

These experiments showed that after single sub-cultures on glycerin bile egg the strain "Bovine Vallée" was not of higher virulence for guinea-pigs than the same strain grown on plain egg.

On the other hand, these authors[2, 21] stated that when successive subcultures were made on bile media the bacilli instead of further increasing in virulence became attenuated at each passage. After 15 passages the bacilli in doses of 1·0 mg. intraperitoneally caused "une tuberculose viscérale compatible pendant plus de cinq mois avec les apparences d'une bonne santé sans amaigrissement." The same inoculation under the skin provoked a slow enlargement of the neighbouring gland; sometimes an abscess formed at the seat of inoculation which opened and then healed. The affection showed no tendency to generalisation. After 42 passages when the strain had been cultivated on bile media for a period of about four years the bacilli appeared to be stablised in virulence for the guinea-pig.

Calmette and Guérin further state that the bile culture of the forty-second passage, although incapable of causing general progressive tuberculosis in the guinea-pig, was extremely virulent for the horse. Two horses aged 3 and 14 years received 5·0 mg. intravenously and succumbed respectively 55 and 73 days later with "des lesions énormes de granulie pulmonaire."

For bovines there was the same march of decreasing virulence as was observed for the guinea-pig. At the second passage 5·0 mg. intravenously provoked a typho-bacillosis without follicular lesions. At the tenth passage a dose of 50·0 mg. was necessary and at the fifteenth 100·0 mg. caused a general disease "d'allure typhique" which was rarely fatal and never accompanied by the formation of lesions.

It was evident from the pathogenic history of the strain that already after only 15 subcultures on bile media, extending over a period of about one year, the strain was no longer capable of producing progressive tuberculosis in calves and guinea-pigs.

In order to ascertain whether other strains of the tubercle bacillus could be as readily modified in this way I began in 1925 the serial cultivation of two strains, one of bovine and one of avian tubercle bacilli, and at a later date added three further strains of bovine and one of human bacilli. These six strains have now been continuously subcultivated on bile media, the transfers being made every two to three weeks, for periods ranging from four to six years. The bile media used have been potato soaked in 5 per cent. glycerin ox-bile and 5 per cent. glycerin egg to which was added before inspissation 10 per cent. (in the early experiments, 7·5 per cent.) ox bile.

The cultures of mammalian tubercle bacilli on the bile egg medium are strikingly different from those on egg without bile. Instead of being dry, coherent, and difficult to emulsify, they are soft, moist, and easily emulsified. After two to three weeks' incubation the growth is shiny, moist, and translucent. On further incubation the growth thickens, becomes opaque, acquires a creamy or a buff colour, and closely resembles a layer of thick paint unevenly spread. In old cultures secondary colonies appear on the surface; in the case of four strains these were minute while in two they were large and varied in form, some being widespread and warty or wrinkled, some heaped up and nodular or umbilicated or crateriform.

On ox bile potato human and avian strains grow as freely as bovine strains and produce very similar growths. After from four to six weeks the growths are moderately thick, opaque, greyish, slightly or definitely creamy and warty on the surface. On magnification they are seen to be composed of small closely aggregated and super-imposed pearly grey colonies. The growth is moist and easily spread.

On transference to ordinary media the bile cultures of mammalian tubercle bacilli again produce dry coherent growths. The modification of cultural characters caused by cultivation on bile media is therefore not permanent.

The virulence of the bile strains has been tested at intervals. All the mammalian strains are still virulent and capable of producing progressive tuberculosis in the guinea-pig after from four to six years' cultivation on bile media; also the avian strain is virulent for the fowl. One strain only, No. 4 bovine virus, after 1308 days on bile media is definitely reduced in virulence, producing in guinea-pigs and rabbits a much more chronic form of tuberculosis than the same strain maintained on egg. This bile-cultivated strain recovered from the chronically infected guinea-pigs produces a severe form of tuberculosis in other guinea-pigs so that one cannot yet speak of a permanent attenuation of the strain. The passage experiments on bile media with the six strains are being continued.

Spontaneous Tuberculosis in Animals Inoculated with B C G.

Rabbits and guinea-pigs inoculated with B C G were, as a rule, kept apart from animals infected with virulent tubercle bacilli. For various reasons this rule was sometimes broken and a few animals were put into houses containing tuberculous animals. As a result one rabbit and two guinea-pigs contracted spontaneous tuberculosis.

1. The rabbit had been inoculated intravenously with 20 mg. of B C G and was killed 460 days after inoculation. The autopsy showed numerous caseous lesions in the lymphoid tissue of the appendix and a few in the solitary follicles of the cæcum. At the back of the left orbit there was a caseous abscess (of periosteal origin) and the left lachrymal gland was almost replaced by caseous nodules. The lungs were crepitant and showed a few minute grey foci. Typical avian cultures were obtained from the appendix, colon, lachrymal gland and orbital abscess. Two fowls inoculated subcutaneously with 15 mg. of one of the strains died in 49 and 52 days of general miliary tuberculosis.

The avian infection in this rabbit was, I think, acquired from two rabbits living in the house at the same time which had been inoculated with a strain of avian tubercle bacilli from a kangaroo.

2. A guinea-pig, one of two which had been inoculated with deep-broth cultures of B C G. Six flasks of broth were inoculated, each with the young growth from one glycerin egg tube, and were incubated for three or more months. There was no apparent multiplication of the bacilli except perhaps in one flask. The granules of culture were collected, emulsified and inoculated subcutaneously into two guinea-pigs which were killed 111 days later. One was found to be perfectly normal. The other showed nothing at the seat of

claimed $175,000 from the estate of one Alexander J. Derbyshire. They lost their suit in the Supreme Court. In 1913 they made another unsuccessful attempt. Now at last they succeed through a new legislative enactment. The property has been increasing in value during the last 50 years and the hospital is richer by more than three million dollars.

THE LÜBECK TRIAL.

(FROM OUR BERLIN CORRESPONDENT.)

(*Concluded from p.* 260.)

THE CASE FOR THE DEFENCE.

COUNSEL for Dr. Altstädt said that his client had gone to Berlin where (he stated) in the Robert Koch Institute B C G was cultivated in a room easily accessible from other rooms of the laboratory; and yet his client was held responsible for the same condition in Lübeck. The death of the first victim—infant G—was not a sufficient reason to stop the further application of the Calmette method as suggested by the public prosecutor. Not his client alone, but other physicians too had believed that that death had nothing to do with the B C G, but was due to congenital tuberculosis. His client had certainly believed B C G to be a virus fixe, but other physicians not concerned in the disaster shared that opinion. Whether that opinion was right or wrong the trial had not decided, but it was the holding of that opinion which had led Dr. Altstädt to introduce the Calmette method in Lübeck. He should not be punished for manslaughter by negligence on account of a possible error on a scientific question. He therefore pleaded for a verdict of not guilty.

Counsel for Prof. Deycke described his client as a man who had devoted his whole life to the welfare of humanity. As a young assistant at the Hamburg General Hospital he had discovered, by bacteriological research, the first cases of cholera at the beginning of the great epidemic of 1893 in that city, and his discovery had contributed to early preventive measures. He had been of opinion that B C G was innocuous and could by no means become altered, a point of view shared, not only by Prof. Calmette, but by medical science in general. Prof. Deycke now regretted that he had not considered Dr. Petroff's contrary opinion, the reason being that these experiments were not believed to be reliable. He was still convinced that contamination of cultures in his laboratory was impossible, and not in point of fact ascertained by the evidence submitted. Prof. Lange, who assumed contamination had come to that view by holding the theory of B C G being invariable—a theory which was beginning however to fade. The court, he said, ought to consider whether the belief that B C G was a virus fixe could be regarded as negligence under the law, all the more as medical experts differed over it. The great number of experts was a special feature of the trial and there was no single question on which they all agreed. He was of opinion that the non-existence of a special laboratory for which his client was especially blamed had nothing to do with the disaster. Finally, in his client's name, he protested against the attack on Prof. Calmette made by counsel for the parents. He asked for a verdict of not guilty.

Prof. Deycke was then allowed some final words. He had nothing, he said, to add to his counsel's remarks; it had been his ill fate to kill and injure many children in the desire to protect them against sickness. If the court came to the conclusion that the disaster had not been caused by force majeure, but by his negligence he was willing to suffer punishment. He begged the court to pronounce a verdict of not guilty for his associates.

THE SENTENCE.

The trial which began on Oct. 13th came to an end on Feb. 6th when sentence as pronounced. Prof. Deycke and Dr. Altstädt were both found guilty of manslaughter by negligence in 68 cases and of injury by negligence in 131 cases; they were sentenced to two years and one and a half years imprisonment respectively. Prof. Klotz and Nurse Schütze were found not guilty and acquitted, the charges against them not being sufficiently proved. In pronouncing the judgment of the court the presiding judge said the court had been convinced that although according to the opinions of some experts B C G vaccine may, under certain conditions, become virulent, the disaster had actually been caused by an exchange of B C G with other virulent bacilli or by contamination. The negligence was found in the fact that Prof. Deycke had prepared the culture in a laboratory where such contamination or exchange was within the reach of possibility. Dr. Altstädt, as director of the Lübeck Health Department, had acted negligently in not having the cultures tested before distribution to patients, and in not immediately stopping that distribution as soon as he had been informed by Prof. Deycke that something was wrong with them.

The sentence was heard by the numerous audience with strong emotion, Prof. Deycke being very popular in Lübeck as a conscientious physician and a member of one of the oldest families in the Hanseatic city.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JAN. 30TH, 1932.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 49 (last week 55); scarlet fever, 1586; diphtheria, 1039; enteric fever, 36; pneumonia, 1557; puerperal fever, 22; puerperal pyrexia, 114; cerebro-spinal fever, 36; acute poliomyelitis, 8; acute polio-encephalitis, 1; encephalitis lethargica, 20; dysentery, 21; ophthalmia neonatorum, 79. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Feb. 2nd–3rd was as follows: Small-pox, 110 under treatment, 3 under observation (last week 124 and 6 respectively); scarlet fever, 1182; diphtheria, 1479; enteric fever, 10; measles, 780; whooping-cough, 331; puerperal fever, 16 (plus 10 babies); encephalitis lethargica, 222; poliomyelitis, 4; "other diseases," 275. At St. Margaret's Hospital there were 20 babies (plus 13 mothers) with ophthalmia neonatorum.

Deaths.—In 117 great towns, including London, there was no death from small-pox or enteric fever, 39 (14) from measles, 6 (2) from scarlet fever, 39 (5) from whooping-cough, 32 (6) from diphtheria, 25 (3) from diarrhœa and enteritis under two years, and 313 (86) from influenza. The figures in parentheses are those for London itself.

The deaths from influenza show a marked drop from the previous week. The total for the year so far amounts to 1458, against 795 for the corresponding period of 1931. Of the great towns Birmingham stands this week much higher with 21 deaths from influenza, Bradford reports 9, Croydon, Liverpool, and Manchester each 7. Manchester reported 6 deaths from measles, Liverpool reported 9 deaths from whooping-cough, Birmingham 7. Diphtheria accounted for 3 deaths each at Blackpool and Salford.

The number of stillbirths notified during the week was 263 (corresponding to a rate of 42 per 1000 births), including 40 in London.

that the principal educational advantages which he attributed to the present system could not be as easily maintained under a system of amalgamation. It is clear, on the other hand, that with a larger body of students to deal with in a particular institution they could be better organised with study groups according to their standing and experience. The absurdity of attempting to teach students in their first hospital year and those preparing for their final examination in the same class would, for example, be avoided. Again, it will occur to many that the slight advantage accruing to the patients from ease of access to a hospital—not a matter of much importance in a compact city like Dublin possessed of a good transport service—is much more than counterbalanced by grave disadvantages. With hospitals of small size diagnosis and treatment are delayed by the impossibility of having at hand an adequate auxiliary staff. The hospitals are adequately—if not excessively—staffed by physicians and surgeons, each of whom, however, by lack of access to a wide field of experience, is debarred from gaining a special knowledge or skill in any special department of medicine or surgery. But the services of a pathologist, of a radiologist, of a biochemist, of an ophthalmic surgeon, of a laryngologist, have to be divided according to the days of the week between two, three, or more hospitals. Not only delay, but relative inefficiency is inevitable, for the physician or surgeon finds it difficult if not impossible to have personal interviews with the specialists to whom he looks for help.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

NATIONAL HEALTH.

REPORTS for the fiscal year 1931 are now coming to hand. Two of these[1] give evidence both of the state of national health and of the efforts being made to improve it. The public health service can boast of a good calendar year 1930 with record low death-rates for tuberculosis (68·5) and diphtheria (4·9) and in most respects a good beginning to 1931. A slight increase of pellagra in the first six months of 1931 (16,385 cases as compared with 13,359 in the corresponding period of the previous year) may possibly be related to the economic depression. "Many requests have reached the Public Health Service for authoritative information as to the effect of the present economic situation upon the public health." The surgeon-general regrets that more complete and comprehensive information could not be supplied, and adds significantly: "It will be recalled that recommendations have been made for several years past that a small appropriation be made for the purpose of developing and stimulating better reporting of the notifiable diseases."

Almost 20,000 passengers and 1597 seamen were certified at domestic ports to be suffering from contagious disease, mental defect, or insanity. Those who have condemned the stringency of the Immigration Act of 1917 will find some excuse for it in the detailed figures here presented. No less than 340 cases of trachoma and 596 cases of venereal disease were discovered among the passengers examined. At European ports of embarkation 41,737 passengers were vaccinated and 38,639 were deloused.

The report of the division of scientific research discloses an astonishing amount of important work now in progress. With specially designed physical apparatus studies are about to be made on the biological action of the whole spectrum of radiation from the highest frequency X rays to electromagnetic radiation. It is hoped of course that some results of practical value in the treatment of cancer may be obtained. Our knowledge in this field is certain to make an important advance. A large programme of biological research in cancer must be added to the above physico-biological programme. It includes studies of resistance and immunity, of the biochemistry of malignant cells, and of susceptibility to malignant growths. All research workers in cancer will wish to inform themselves in detail from this interesting report of the plans and progress of the "office of field investigations of cancer" housed at the Harvard Medical School. The results of some other investigations of the public health service, as for instance, the studies on Rocky Mountain spotted fever, have already been described in my letters.

The report of the chief of the Children's Bureau is also charged with accounts of scientific investigation. A study of 7537 maternal deaths in 15 States shows plainly the correlation between deaths from "albuminuria and convulsions" and lack of prenatal care. It also shows that the value of prenatal care is little appreciated. Less than 1 per cent. of 4570 women who died in childbirth or in the last three months of pregnancy had received "really adequate" prenatal care. A study of neonatal deaths lays much emphasis on the importance of prematurity as a cause, but does not consider (at least in this report) the possibility that an hereditary or early developmental defect may be the cause both of prematurity and of neonatal death. Studies on the influence of the economic depression show that family relief expenditures in American cities increased 89 per cent. in 1930 over those of the previous year. In certain localities depending upon coal mining and small industries it is found that "local public and private resources . . . are quite inadequate . . . to meet the needs of the children of the unemployed or under-employed men." The report contains a very complete account of State legislation (both successful and attempted laws) which deal with children, including child labour, minimum age of marriage, and juvenile courts.

COMPULSORY HEALTH INSURANCE AT A UNIVERSITY.

The principle of health insurance is implicit in a scheme for health service to staff and employees of the clinics group at the University of Chicago, approved by the board of trustees. One dollar a month is to be deducted from the salaries of all employees for their expense of this service. Operations for the removal of defects discovered at the time of employment are not included in the service. But defects found at this time if they are liable to interfere with proper performance of duties, must be remedied within three months at the employee's own expense or on their own responsibility. After one year's employment under the scheme defects will be remedied free of charge. Two months' hospital care and treatment for conditions usually treated in the University of Chicago clinics is included in the benefits. All employees appointed or reappointed after Dec. 1st, 1931, are obliged to participate in the scheme.

WINDFALL IN PHILADELPHIA.

The Pennsylvania Hospital has received a windfall which should be welcome at this time. In 1879 they of a systematic effort in Scotland to search out the flaws in the Insurance Acts. Some insurance practitioners have protested against the implied criticism and their protest may have considerable force. But when the incidence of certified sickness assumes the proportion of one in two of the lives at risk, certain questions suggest themselves: first, is this a genuine excess or is it due to too facile certification? Secondly, is the insurance system made to carry too heavy a load? There is a third question: How can the insured person secure the value of the public hospitals and clinics, official and voluntary, without being taxed twice? These are fundamental questions, and it will be interesting to watch how the Scottish Department will develop its methods of solving them. When the figures already collected are set forth in a full public document we shall possess genuine data for an estimate of the whole system.

A Conference on Certification in Rutland.

Medical practitioners in Rutland met representatives of approved societies at a conference held recently at Stamford, and reported in the *National Insurance Gazette* for Jan. 30th. It was decided not to discuss memorandum 329 I.G. as a whole, but to consider a few contentious points in administrative procedure. The chairman of the conference has summarised the discussion under headings, of which we quote the following:—

RELATIVE INCAPACITY.—The case of an insured person normally engaged in heavy work—e.g., an ironstone quarryman, who is incapable of that work and in receipt of benefit, but who has entered a stage of convalescence.

Answer: It appeared that societies would welcome information from practitioners when an insured person has so far recovered as to be able to do light work, although unfit for his usual occupation, and that practitioners could convey this information to societies in these cases by using the remarks space on medical certificates.

ANY WORK TO GO TO?—Should a doctor have any regard to the point as to whether a patient has any work to go to on recovery from illness?

Answer: It was considered that the practitioner should have no regard as to whether a patient has work to go to on recovery from illness.

SUSPECTED MALINGERING.—In cases of doubtful incapacity for work or suspected malingering, would medical practitioners prefer to reply to an inquiry from the society before the society refers the case to the regional medical officer?

Answer: It appeared that the medical practitioners would be willing to reply to such an inquiry, although it was remarked that this would entail further clerical work on the practitioner, which was undesirable.

REFERENCE TO R.M.O.—Having regard to the fact that practitioners can refer cases to the regional medical officer without payment of a reference fee, whilst a society has to pay 1*s*. 6*d*. in every case, could practitioners be induced to make greater use of the regional medical officer?

Answer: Several members of the medical profession stated that they were unaware that societies were subject to the charge mentioned in respect of references made by them. References by practitioners necessitated completion of a somewhat lengthy form and again increased clerical work. Some practitioners inserted the words "Refer to R.M.O." on certificates, but some societies took no action on this remark. It was felt that further precautions should also be taken by all concerned to ensure that the patient did not become aware as to whether he was referred by the society or the practitioner.

THE SICK VISITOR.—Medical certificates are to be regarded by societies as part evidence of incapacity only, and the society is under an obligation to satisfy itself that incapacity does exist—i.e., calls by sick visitor.

Answer: It appeared that this point was raised in order to acquaint medical practitioners of this obligation placed on societies as it was considered that, in the absence of knowledge on this point, there was a danger of offence being taken by practitioners against a duty which societies are called upon to perform.

Range of Service and Emergency Treatment.

Addresses are being given this winter in London to students and recently qualified men on insurance practice by lecturers thoroughly conversant with all the ramifications of the regulations. Dr. E. A. Gregg addressed U.C.H. men, and Dr. A. F. Heald St. George's men in December, and last month Dr. R. G. Chase gave a lecture at St. Bartholomew's Hospital which was reported in the Supplement of the *British Medical Journal* for Jan. 23rd. Dealing with the range of service in insurance practice this included, he said, all proper and necessary medical services other than those requiring special skill or experience of a degree or kind which general practitioners could not, as a class—that last phrase was important—reasonably be expected to possess. Those to whom he was speaking, he remarked, were about to go out into general practice with a knowledge of the latest methods of diagnosis and treatment, but the position of the older qualified men had to be remembered, men who had been in practice for many years, and who, perhaps, were not familiar with the latest methods. The range of service implied, not that which a particular man was capable of undertaking, but the kind of service of which general practitioners as a class were capable. A necessary qualification to this, however, was emergency treatment. In an emergency the practitioner might be called on for quite exceptional services. For example, in a case of laryngeal obstruction, it was the practitioner's duty, assuming, of course, that there was no possibility of getting the patient into skilled hands in time to save his life, to do a tracheotomy, whether he had special skill or not. Dr. Chase recalled the case of a doctor—a capable surgeon—who reported on the usual form that he had operated on a case of appendicitis which was of an urgent character. But he was not allowed to charge for the operation, because, although it was one beyond the skill commonly possessed by the general practitioner, he had reported it as an emergency.

Insurance Practitioner as Social Reformer.

Dr. G. de Swietochowski regards[1] the insurance medical service as the chief agency of social reform in the near future. Doctors, he says, have the best qualifications that men can have to make successful leaders amongst social reformers. They are intimately associated with large numbers of people, the character of the relationship being naturally a friendly one and at the same time a confidential one; they have the education and standing; above all they have the confidence of millions of people whose needs they know well, and they have the power to say and do things like no other men in the country. More use, he thinks, should be made of the link which has been established between the doctors and the government through the national health insurance system in order to introduce new methods and break with the old ones. The support of the government should enable insurance practitioners to exercise a gentle

PANEL AND CONTRACT PRACTICE

A State of Mind.

WHILE so much is being written in letters to our journals, in official memoranda, and in leading articles, about the sins of commission and omission on the part of approved societies or practitioners, the point of view of the insured person has nowhere been stressed. In his recent valuation report the Government Actuary impressed on the authorities responsible the importance of stricter supervision over certificates and claims for sickness benefit. He implies that we must get back to a standard level, and he indicates that the experience of ten years ago is a fair standard to work to. The question is, Can it be done? Such a view regards the present economic stress as a temporary phase, and assumes that we shall return to an era of prosperity such as the fat years 1921–23. But who is to say how much of the change in our economic life is permanent; has there not been concurrent change in mind and outlook of the people? It is not merely the doctors and the approved societies who are concerned in the question of increased claims for either sickness or unemployment benefits. People are claiming more frequently than they used to do, and not only of necessity. Ideas have changed. Claims are made as a right. The community or State is looked to for help when distress is caused by changes in economic conditions. So with health. People are exhorted to be healthy and provided with the means to do so in public health services. Why, it is argued, does not the State go further and provide something for economic loss. In this state of mind they do not regard their claims either on sickness or unemployment funds to be improperly made. The pressure of insured persons has greatly increased, and this point is stressed in the answer made by the Insurance Acts Committee to the Government memorandum, when reasons were given for asserting that the most important cause of the increase in sickness claims is the larger proportion of those who rightly claim to-day in comparison with those who claimed, say, ten years ago. The main factors in this change of mind are briefly:—

Propaganda by insurance committees and others, showing the wisdom of exercising rights.

Knowledge of rights, including the effect which the elimination of the first three days of incapacity has on future claims during the year.

Diminution of prejudice against exercising these rights.

Economic necessity for claiming rights.

Increased advice, and in some cases pressure from approved societies' agents, works officers, welfare workers, and others to claim benefits.

Increase in the scale of sickness benefit in some societies, increasing the inducement to claim benefits.

Finally, there is the higher standard of what constitutes health on the part of the whole community, which applies especially to pregnancy and the post-partum period.

Morbidity Statistics in Scotland.

As the result of a new scheme for morbidity statistics full particulars of every certificate issued in Scotland are now being recorded by the Scottish Department of Health, with the result of making it possible to undertake a systematic analysis of the sickness experience of the community. During the 12 months ended June 30th, 1931, notifications received from approved societies show that 392,335 first certificates were issued in respect of a total insured population on doctors' lists amounting to 1,779,191, that is, one first certificate for about every four insured persons. In particular panels first certificates are almost as high as one in every two insured persons. The average duration of the certified illnesses completed during this period was 25·95 days; this does not include cases of chronic illness whose duration extends beyond the period named. In the aggregate not less than 19,000,000 days of incapacity for work—representing an expenditure on benefits of about £2,000,000—have been certified by Scottish insurance practitioners for the patients under their care during the year in question. The causes of incapacity most frequently recorded are minor diseases of the upper respiratory tract accidents, and influenza (each of which accounts fo more than 10 per cent. of total incapacities), inflammatory and suppurative conditions of the skin and subcutaneous tissues, gastritis, and bronchitis (each of which accounts for more than 5 per cent incapacities). Of the total days lost, the greates proportion are due to accidents, bronchitis, rheumatism (undefined), inflammatory and suppurativ conditions of the skin and subcutaneous tissues gastritis, influenza, and minor diseases of the uppe respiratory tract—in that order of importance.

In the incidence of incapacity, single women ar equal to men; but married women are certified a incapable of work twice as frequently as men or singl women. The average duration of illness, irrespectiv of cause, in married women is, moreover, 36 per cent higher than that for men. The average for singl women is also in excess of that for men by 21 pe cent. In married women, 20 per cent. of the whol sickness loss is attributed to pregnancy and it associated conditions or complications. And ther *is another very striking fact: in both men and wome* incapacity for work is relatively most frequent a ages under 20 years, and the difference between me and women in respect of sickness incidence is relativel greatest at the earlier ages. It is obvious that th strain of work falls heaviest on the younger lives.

Rural areas show a lower incidence of incapacit but a higher average duration than urban area Of this longer duration part at least can be assigne to the lower proportion of short-duration illnesse in rural areas. In one area with a high certificatio experience during the first six months of the operatio of the scheme, it was ascertained that many of th certificates issued were due to one particular cause group of incapacity which, on further examination was related to the method of work of the operative in the particular occupation in that area. A simp protective device would, it is thought, effect substantial saving of working capacity.

A CIRCULAR LETTER TO SCOTTISH PRACTITIONERS.

The Scottish Department has issued a circula letter to insurance practitioners asking for the coöperation in exploring methods for the reductio of this unprecedented sickness. Many new fact have already been brought to light by the inquiry— e.g., the frequency of incapacity for work at the earlie ages. Here is a problem for detailed research. It recognised that the frequency in the issue and duratio of claims must vary from factors outside the contro of practitioners, and a few areas where this variatio is greatest are to be specially investigated. Th letter must be regarded as an administrative documen of the first importance, marking indeed the beginnin of a systematic effort in Scotland to search out the flaws in the Insurance Acts. Some insurance practitioners have protested against the implied criticism and their protest may have considerable force. But when the incidence of certified sickness assumes the proportion of one in two of the lives at risk, certain questions suggest themselves: first, is this a genuine excess or is it due to too facile certification? Secondly, is the insurance system made to carry too heavy a load? There is a third question: How can the insured person secure the value of the public hospitals and clinics, official and voluntary, without being taxed twice? These are fundamental questions, and it will be interesting to watch how the Scottish Department will develop its methods of solving them. When the figures already collected are set forth in a full public document we shall possess genuine data for an estimate of the whole system.

A Conference on Certification in Rutland.

Medical practitioners in Rutland met representatives of approved societies at a conference held recently at Stamford, and reported in the *National Insurance Gazette* for Jan. 30th. It was decided not to discuss memorandum 329 I.G. as a whole, but to consider a few contentious points in administrative procedure. The chairman of the conference has summarised the discussion under headings, of which we quote the following:—

RELATIVE INCAPACITY.—The case of an insured person normally engaged in heavy work—e.g., an ironstone quarryman, who is incapable of that work and in receipt of benefit, but who has entered a stage of convalescence.

Answer: It appeared that societies would welcome information from practitioners when an insured person has so far recovered as to be able to do light work, although unfit for his usual occupation, and that practitioners could convey this information to societies in these cases by using the remarks space on medical certificates.

ANY WORK TO GO TO?—Should a doctor have any regard to the point as to whether a patient has any work to go to on recovery from illness?

Answer: It was considered that the practitioner should have no regard as to whether a patient has work to go to on recovery from illness.

SUSPECTED MALINGERING.—In cases of doubtful incapacity for work or suspected malingering, would medical practitioners prefer to reply to an inquiry from the society before the society refers the case to the regional medical officer?

Answer: It appeared that the medical practitioners would be willing to reply to such an inquiry, although it was remarked that this would entail further clerical work on the practitioner, which was undesirable.

REFERENCE TO R.M.O.—Having regard to the fact that practitioners can refer cases to the regional medical officer without payment of a reference fee, whilst a society has to pay 1*s.* 6*d.* in every case, could practitioners be induced to make greater use of the regional medical officer?

Answer: Several members of the medical profession stated that they were unaware that societies were subject to the charge mentioned in respect of references made by them. References by practitioners necessitated completion of a somewhat lengthy form and again increased clerical work. Some practitioners inserted the words "Refer to R.M.O." on certificates, but some societies took no action on this remark. It was felt that further precautions should also be taken by all concerned to ensure that the patient did not become aware as to whether he was referred by the society or the practitioner.

THE SICK VISITOR.—Medical certificates are to be regarded by societies as part evidence of incapacity only, and the society is under an obligation to satisfy itself that incapacity does exist—i.e., calls by sick visitor.

Answer: It appeared that this point was raised in order to acquaint medical practitioners of this obligation placed on societies as it was considered that, in the absence of knowledge on this point, there was a danger of offence being taken by practitioners against a duty which societies are called upon to perform.

Range of Service and Emergency Treatment.

Addresses are being given this winter in London to students and recently qualified men on insurance practice by lecturers thoroughly conversant with all the ramifications of the regulations. Dr. E. A. Gregg addressed U.C.H. men, and Dr. A. F. Heald St. George's men in December, and last month Dr. R. G. Chase gave a lecture at St. Bartholomew's Hospital which was reported in the Supplement of the *British Medical Journal* for Jan. 23rd. Dealing with the range of service in insurance practice this included, he said, all proper and necessary medical services other than those requiring special skill or experience of a degree or kind which general practitioners could not, as a class—that last phrase was important—reasonably be expected to possess. Those to whom he was speaking, he remarked, were about to go out into general practice with a knowledge of the latest methods of diagnosis and treatment, but the position of the older qualified men had to be remembered, men who had been in practice for many years, and who, perhaps, were not familiar with the latest methods. The range of service implied, not that which a particular man was capable of undertaking, but the kind of service of which general practitioners as a class were capable. A necessary qualification to this, however, was emergency treatment. In an emergency the practitioner might be called on for quite exceptional services. For example, in a case of laryngeal obstruction, it was the practitioner's duty, assuming, of course, that there was no possibility of getting the patient into skilled hands in time to save his life, to do a tracheotomy, whether he had special skill or not. Dr. Chase recalled the case of a doctor—a capable surgeon—who reported on the usual form that he had operated on a case of appendicitis which was of an urgent character. But he was not allowed to charge for the operation, because, although it was one beyond the skill commonly possessed by the general practitioner, he had reported it as an emergency.

Insurance Practitioner as Social Reformer.

Dr. G. de Swietochowski regards[1] the insurance medical service as the chief agency of social reform in the near future. Doctors, he says, have the best qualifications that men can have to make successful leaders amongst social reformers. They are intimately associated with large numbers of people, the character of the relationship being naturally a friendly one and at the same time a confidential one; they have the education and standing; above all they have the confidence of millions of people whose needs they know well, and they have the power to say and do things like no other men in the country. More use, he thinks, should be made of the link which has been established between the doctors and the government through the national health insurance system in order to introduce new methods and break with the old ones. The support of the government should enable insurance practitioners to exercise a gentle

PANEL AND CONTRACT PRACTICE

A State of Mind.

WHILE so much is being written in letters to our journals, in official memoranda, and in leading articles, about the sins of commission and omission on the part of approved societies or practitioners, the point of view of the insured person has nowhere been stressed. In his recent valuation report the Government Actuary impressed on the authorities responsible the importance of stricter supervision over certificates and claims for sickness benefit. He implies that we must get back to a standard level, and he indicates that the experience of ten years ago is a fair standard to work to. The question is, Can it be done? Such a view regards the present economic stress as a temporary phase, and assumes that we shall return to an era of prosperity such as the fat years 1921–23. But who is to say how much of the change in our economic life is permanent; has there not been concurrent change in mind and outlook of the people? It is not merely the doctors and the approved societies who are concerned in the question of increased claims for either sickness or unemployment benefits. People are claiming more frequently than they used to do, and not only of necessity. Ideas have changed. Claims are made as a right. The community or State is looked to for help when distress is caused by changes in economic conditions. So with health. People are exhorted to be healthy and provided with the means to do so in public health services. Why, it is argued, does not the State go further and provide something for economic loss. In this state of mind they do not regard their claims either on sickness or unemployment funds to be improperly made. The pressure of insured persons has greatly increased, and this point is stressed in the answer made by the Insurance Acts Committee to the Government memorandum, when reasons were given for asserting that the most important cause of the increase in sickness claims is the larger proportion of those who rightly claim to-day in comparison with those who claimed, say, ten years ago. The main factors in this change of mind are briefly:—

Propaganda by insurance committees and others, showing the wisdom of exercising rights.

Knowledge of rights, including the effect which the elimination of the first three days of incapacity has on future claims during the year.

Diminution of prejudice against exercising these rights.

Economic necessity for claiming rights.

Increased advice, and in some cases pressure from approved societies' agents, works officers, welfare workers, and others to claim benefits.

Increase in the scale of sickness benefit in some societies, increasing the inducement to claim benefits.

Finally, there is the higher standard of what constitutes health on the part of the whole community, which applies especially to pregnancy and the post-partum period.

Morbidity Statistics in Scotland.

As the result of a new scheme for morbidity statistics full particulars of every certificate issued in Scotland are now being recorded by the Scottish Department of Health, with the result of making it possible to undertake a systematic analysis of the sickness experience of the community. During the 12 months ended June 30th, 1931, notifications received from approved societies show that 392,335 first certificates were issued in respect of a total insured population on doctors' lists amounting to 1,779,191, that is, one first certificate for about every four insured persons. In particular panels first certificates are almost as high as one in every two insured persons. The average duration of the certified illnesses completed during this period was 25·95 days; this does not include cases of chronic illness whose duration extends beyond the period named. In the aggregate not less than 19,000,000 days of incapacity for work—representing an expenditure on benefits of about £2,000,000—have been certified by Scottish insurance practitioners for the patients under their care during the year in question. The causes of incapacity most frequently recorded are minor diseases of the upper respiratory tract, accidents, and influenza (each of which accounts for more than 10 per cent. of total incapacities), inflammatory and suppurative conditions of the skin and subcutaneous tissues, gastritis, and bronchitis (each of which accounts for more than 5 per cent. incapacities). Of the total days lost, the greatest proportion are due to accidents, bronchitis, rheumatism (undefined), inflammatory and suppurative conditions of the skin and subcutaneous tissues, gastritis, influenza, and minor diseases of the upper respiratory tract—in that order of importance.

In the incidence of incapacity, single women are equal to men; but married women are certified as incapable of work twice as frequently as men or single women. The average duration of illness, irrespective of cause, in married women is, moreover, 36 per cent. higher than that for men. The average for single women is also in excess of that for men by 21 per cent. In married women, 20 per cent. of the whole sickness loss is attributed to pregnancy and its associated conditions or complications. And there is another very striking fact: in both men and women incapacity for work is relatively most frequent at ages under 20 years, and the difference between men and women in respect of sickness incidence is relatively greatest at the earlier ages. It is obvious that the strain of work falls heaviest on the younger lives.

Rural areas show a lower incidence of incapacity but a higher average duration than urban areas. Of this longer duration part at least can be assigned to the lower proportion of short-duration illnesses in rural areas. In one area with a high certification experience during the first six months of the operation of the scheme, it was ascertained that many of the certificates issued were due to one particular cause-group of incapacity which, on further examination, was related to the method of work of the operatives in the particular occupation in that area. A simple protective device would, it is thought, effect a substantial saving of working capacity.

A CIRCULAR LETTER TO SCOTTISH PRACTITIONERS.

The Scottish Department has issued a circular letter to insurance practitioners asking for their coöperation in exploring methods for the reduction of this unprecedented sickness. Many new facts have already been brought to light by the inquiry—e.g., the frequency of incapacity for work at the earlier ages. Here is a problem for detailed research. It is recognised that the frequency in the issue and duration of claims must vary from factors outside the control of practitioners, and a few areas where this variation is greatest are to be specially investigated. The letter must be regarded as an administrative document of the first importance, marking indeed the beginning "explain" the "cause of life." Surely, the proper question for pathology to try to answer is not "what is the cause of cancer?" but "what is the biological mechanism of tumour formation?"

I am, Sir, yours faithfully,
G. W. NICHOLSON.
Guy's Hospital, S.E., Feb. 7th, 1932.

To the Editor of THE LANCET.

SIR,—Mr. J. J. M. Shaw, in his first article, suggests the possibility of the lowering of the anti-epithelial resistance in pregnancy to permit the invasion of the trophoblast. At that stage there is no continuity of tissue between uterus and ovum and nothing, one may suppose, to indicate the presence of a stranger requiring such accommodation. On the other hand the trophoblast, having eroded its way into the required position, disappears. May it not be that its presence acts as a stimulus to the production of an antibody which effectively destroys the invader, the occasional failure of such a reaction permitting chorion epethelioma? The blood-serum of early pregnancy might possibly show some action on living cancer cells.

I am, Sir, yours faithfully,
P. L. W. WILLIAMS, F.R.C.S. Edin.
Padstow, Feb. 5th, 1932.

THE SPAHLINGER REMEDIES.

To the Editor of THE LANCET.

SIR,—May I be allowed to clear up some of the misapprehensions which have crept into your leading article of Feb. 6th. It is quite true that, after having sent several commissions—one of which included the late Prof. Ritchie—to investigate my work, the British Red Cross offered me a sum of £30,000 for the right to distribute my preparations in the British Isles. Under the agreement I had one year within which to decide whether I was able to supply the large number of doses stipulated for each year. I found it impossible within that time to simplify the methods of production, as I had hoped, sufficiently to supply these large quantities; and therefore I availed myself of a clause in the agreement providing for its determination upon repayment, which I duly made, of the sum received plus interest. I am very anxious that the truth about the Red Cross agreement should be known in view of the absurd stories which have been circulated on that subject. When the Ministry of Health offered me facilities for "an independent experimental trial," my supply of complete preparations was exhausted through lack of funds, and that fact is officially recorded by the Ministry.

Coming to your comments on my formula, in which you find certain "lacunæ," I should like to say that I purposely refrained from describing any technical processes or data with which bacteriologists are familiar, because I was anxious not to be accused of belittling the knowledge and technique of contemporary research workers. At the same time I took pains to describe my method fully enough to enable competent bacteriologists to reproduce my vaccines. Let me, however, reply quite briefly to the points raised by you:

1. It is not usual to find "secondary organisms" in bovine tuberculous lesions; and with moderate skill, tubercle bacilli can be isolated from human lesions without recourse to "acid or alkali to destroy any stray secondary organisms, such as is the usual practice nowadays."

2. You ask what organs or tissues I use. Personally I prefer defibrinated blood, serum, or ascitic fluid. I only mentioned organ and tissue extracts in order to explain that these could also be used as media—as I have experimentally verified—provided they supply a specific *unaltered native* bovine or human fluid to the tubercle bacillus. For methods of extraction and filtration of organs and tissues I would refer to the orthodox text-books on the subject.

3. I do not restrict the use of glycerine, glucose, peptone, or distilled water (not "saline" as you say) to the "cultivation of human strains." These substances can also be used for the cultivation of bovine strains.

4. The "method of removal of oxygen" I did not describe in detail, because there are several and those are part of the usual bacteriological routine, when dealing with anaerobic conditions, or with the preparation of stable standards, or with toxins which easily oxidise, &c. I have made emulsions in vacuo—as you suggest—and in the presence of hydrogen with equally good results.

5. As to the "method of estimating the strength of the bacterial emulsion" may I explain that the emulsion is prepared in large enough quantities to be weighed in a sterile manner. The amount of vaccinating material can therefore be determined in fractions of weight. This point concerns not the method of preparation, but the application of the vaccine—i.e., the dosage. The dosage varies according to the degree of immunity required in the vaccinated animals and the severity of the infection to which such animals are subjected.

I intend shortly to publish the records of my experiments on cattle, giving complete details as to dosage, nature of antigens used in each test, number of injections, reactions, temperatures, autopsies, &c. The comparative results of these tests throw considerable light on immunity, allergy, and resistance increased or diminished by specific means.

I am, Sir, yours faithfully,
London, Feb. 9th, 1932. H. SPAHLINGER.

BRILLIANT GREEN FOR SYCOSIS.

To the Editor of THE LANCET.

SIR,—In your annotation with this title in the issue of Jan. 23rd (p. 202) you quote Prof. Senin as having found this dye a reliable remedy for sycosis, and myself as having studied its bactericidal action in high dilutions on streptococci. The letter of Dr. R. Prosser White (Jan. 30th, p. 261), commenting on this, attributes the virtues of Prof. Senin's brilliant green solution "largely" to the alcohol which it contains, and states further that alcohol is also "the chief active agent in the antiseptic use of tincture of iodine and picric acid." I cannot imagine that Dr. Prosser White has any authority for this statement. Alcohol is a weak germicide, as might naturally be expected from the fact that it is actually produced by bacterial action. My own results, detailed in the paper to which you referred, indicate that brilliant green, iodine, and picric acid are respectively 2000, 180, and 400 times more powerful as germicides than alcohol, judged by the maximum dilutions at which they were effective under the conditions of the tests made. That the conditions of practical use will reduce their efficiency is certain, but the same conditions militate against the successful action of alcohol, with the added disadvantage that evaporation terminates its action within a few minutes.

I draw attention to Dr. Prosser White's statement because it exemplifies an attitude which seems to me to stand in the way of progress in the use of germicides. The extraordinary bactericidal properties of brilliant green have been demonstrated repeatedly in the laboratory; by Prof. Senin's pressure on their patients without the fear of losing them. He adds :—

> “ In this way we may some day be able to tackle the everlasting craving for medicines, pills, and lotions. We could perhaps even face the question of drink without the fear of a revolution. If the whole medical profession lays down its views frankly, resolves unanimously to adhere to its principles and is backed by the supreme executive of the country, no great difficulties can arise. Whereas if undertaken by single individuals all such efforts are nipped in the bud. Even the hospitals in order to remain popular have still to keep up unnecessarily large supplies of practically useless stuff.”

Looking back, he says, we must admit that things have improved a great deal, especially through schools and communal legislation ; the partial prohibition of smoking and spitting in public places, followed by the anti-litter campaign as well as the very modern anti-dog-and-pavement measures are all to the good. But why should *personal* dirt still enjoy the privilege of going about unpunished ? Surely, sooner or later this will be dealt with by a definite and separate legislation. The conditions in factories and workrooms, though vastly improved, still offer room for further amelioration. But the conditions of people's homes, their habits and customs and superstitious beliefs form a rock against which many good intentions are shattered to atoms. Here, he suggests, coöperation of government and a well-organised medical profession might introduce reforms of greater national importance even than those expected from and only partly realised by the National Health Insurance Acts.

CORRESPONDENCE

THE MECHANISM OF TUMOUR FORMATION

To the Editor of THE LANCET.

SIR,—May I express my admiration of Mr. J. J. M. Shaw's paper on the Ætiology of Cancer in recent numbers of THE LANCET ? It increases knowledge and is very opportune. Mr. Shaw argues truly, as I believe, that one “ cause ” alone will not account for tumour formation. Nor is there a logical or biological necessity that it should. The most superficial analysis of causation—as it concerns the living body—distinguishes two factors or groups of factors : the factor of realisation or the *stimulus ;* and the factor of determination or the *reaction* of the organism. The stimulus is extrinsic to the reacting part, regardless of its nature and origin. Its action is limited to inducing the reaction. The very nature and characters of the reaction are determined by the “ constitution ” of the organism, which means, in the end, its physico-chemical composition. Growth and development and, in short, all vital phenomena, are innate reactions to extrinsic stimuli. This is their mechanism, or “ cause,” in the eyes of biology.

Tumour formation is a manifestation of life when all is said and done. Like all vital phenomena it is an *innate* reaction to an extrinsic stimulus. I submit that knowledge of the latter is sound and adequate, though not complete. It is, as duly emphasised by Mr. Shaw, not one single stimulus, but one of many stimuli : from living parasites through introduced chemical substances and physical agents to products of metabolism of the body itself. Every one of these is followed by tumour formation. Their action as factors of realisation is demonstrated. What more can pathology do or be asked to do than to progress on these lines ?

Much less is known of the innate reactions, the fons et origo of tumour formation. Now tumour formation is suggestively like physiological growth and development. It is (1) reaction to extrinsic stimuli, (2) proliferation and differentiation of cells capable of these functions, (3) consequent acquisition of new characters, (4) maintenance, and (5) transmission to future cell generations of the characters thus acquired. All these are subject to control and modification by the organism—even in tumour formation much more widely than generally admitted. I would draw particular attention to Nos. 4 and 5. They represent the so-called autonomy of tumours. In its persistence long after the factor of realisation can often be shown to have ceased to act, and in its essentially “ intrinsic ” manner of growth by proliferation of its own cells alone, an established tumour differs radically from a reaction to an infection, but agrees with every somatic organ. I find it impossible —I use the word advisedly—to regard tumour formation otherwise than as a *developmental* sequence ; delayed and pathological development, if you please, but development nevertheless.

There is no necessity for the assumption of a superadded *new* reaction in tumour formation, in the sense that it is without parallel in physiological development, as Mr. Shaw is careful to indicate. Tumour formation is “ new growth ” or “ neoplasia ” simply in the sense that the liver or kidneys arise anew in the embryo. The same essential mechanism produces them all. Instead of morbid and unnatural, tumour formation is biological and natural, the expression of a physiological “ potency ” of every not fully differentiated cell. The factor of realisation alone is abnormal and pathological. Tumour formation is one of alternative innate reactions, the other of which is proliferation followed by differentiation as a physiological tissue, in wear and tear and in compensation for accidental loss, &c. It is the segregation of ever-present alternative potencies, as induced or realised by stimulation. This I regard as the *mechanism of tumour formation,* just as it is the mechanism of development and growth. The precise nature of its component reactions and their results are questions mainly for biology, and for chemistry and physics in the last resort. Many are beginning to be known.

We should bear in mind that tumour formation is the expression of a much less simple biological mechanism than the immediate reaction to an extrinsic stimulus. The generally enormous latent period of occupational cancer and of experimental tumour formation indicates this. Just as the advent of the kidneys, to take an example, is “ prepared ” by a long sequence of reactions in development, demonstrably beginning with metameric segmentation of the mesoderm if not sooner, and in the absence of any one of which there are no kidneys, so it may well be that tumour formation is the last of many successive reactions, the effect by summation of all those that have gone before.

I conclude that we know just as much of tumour formation as we can expect or be expected to know. Our knowledge is a pretty accurate measure of our ignorance of the mechanism of development and growth. Biology freely admits incompetence to very likely during an anticyclone, when the denser air with the higher barometer buoys us up more, so we walk with less exertion than on a damp cold day with a low barometer—a day we describe as "heavy," though cubic foot for cubic foot the air is lighter; it is we who are less buoyed up, it is we who are heavier; and, besides, air saturated with moisture has a higher specific heat, and so more chilling effect. What we want is more observations of the association of certain meteorological conditions with increase or decrease of illness. Another question to be answered is the period of incubation or invasion of a nosological effect. It used to be said that as a cyclone swept over the United States, so it was followed by doctors' claims for medical treatment of the pensioners whose rheumatic pains had become exacerbated as the low pressure area reached them. But that was some years ago, and I have not heard about that lately. There is much more to learn about the influence of weather on health. It is a pity more detailed observations are not made.

I am, Sir, yours faithfully,

Southborough, Jan. 30th, 1932. W. E. HOME.

CANCER OF THE LUNG.

To the Editor of THE LANCET.

SIR,—In a letter published in your issue of Jan. 30th, Dr. Ellman expresses surprise that no reference was made to a book by Dr. Maurice Davidson in an annotation on cancer of the lung published in your issue of Jan. 23rd. Are we not too apt to overlook important work which is done in this country and to place too much importance on foreign medical literature? The amount of literature is so appalling that its very size is apt to clog rather than hasten the wheels of progress.

I am reminded of a review of some medical work in which the author was criticised for failing to give reference to some foreign work of minor importance. I noticed that the author had also failed to give any reference to a recent and important English work on the same subject, but upon this fact the reviewer omitted to comment. It has been said that in England one has but to add "Offski" to one's name to get a following, and it is certainly a peculiarity of the English to belittle themselves. Only the other day I read in an evening paper complaints about the smoke or dirt in the sleeping-cars of English railways. In America they find it necessary to use wire gauze netting over the railway carriage windows, and even this fails to keep out the smuts. On the continent the trains, and even the luxury trains in which I have travelled, are no cleaner and undoubtedly far less steady than are the trains in this country, yet the average Englishman is always ready to compare his railway or other services unfavourably with other countries. If one pointed out to an American that the trains in that country started and stopped with a series of jerks like an old-fashioned luggage train he would be genuinely offended. As far as I am aware, in no other country but England do people take a delight in belittling themselves.

It would be interesting to hear what modern psychologists have to say about it. I have heard it suggested that it is a form of superiority complex; the Englishman really being completely convinced that he and his country are in every way superior to all others.—I am, Sir, yours faithfully,

L. S. T. BURRELL.

Chandos-street, Cavendish-square, W., Feb. 1st, 1932.

THE CAUSATION OF CHRONIC GASTRO-DUODENAL ULCER.

To the Editor of THE LANCET.

SIR,—I am very grateful to you for the review of my book which appeared in your issue of Jan. 30th (p. 248), and perhaps you will permit me to comment on some of the points raised by your reviewer. I agree that experimental proof in support of my theory would have clinched my argument, but is it always possible or even necessary to prove experimentally a theory before publishing it? I may add, however, that I am at present engaged in experiments which I hope to bring to a successful conclusion, and which will include the verification of G. M. Smith's work (*Journal of Medical Research*, 1914, xxx., 147) quoted at length in my book and which I consider to be of crucial importance.

Your reviewer also says that admittedly good results have been obtained by methods which are partially or wholly opposed to my theory. I think that most general practitioners and all surgeons will refute the first part of this statement. As to the second part, I have endeavoured to show that *two* factors are concerned in the production of peptic ulcers—namely, (1) bile, and (2) hydrochloric acid, and since present-day medicinal treatment consists mainly in the administration of large and frequent doses of alkali, it will be obvious that this treatment abolishes the essential acid factor; hence the temporary improvements and so-called cures which only last as long as treatment is persevered in.

Although your reviewer has not discussed the details of my theory, perhaps you will allow me to mention that before embarking on the involved problem of the mechanism of the formation of chronic peptic ulcers, I have postulated a new conception of the pathology to differentiate between the acute and chronic peptic ulcer which, in my opinion, must form the starting point in the study of this most urgent problem.

I am, Sir, yours faithfully,

J. JACQUES SPIRA.

Half Moon-street, W., Feb. 6th, 1932.

TUBAL PREGNANCY.

To the Editor of THE LANCET.

SIR,—Before you in your wisdom close this correspondence, may I say that my clinical note was as brief as possible because I merely wished to draw attention to the discoloration of the abdominal wall, and therefore did not give a detailed description of the operation.

Thanks to the courtesy of Prof. Miles H. Phillips, I now know that the sign is rare, may have no direct connexion with the presence of blood in the peritoneal cavity, and indeed may occur where there is no hæmorrhage. Prof. Phillips also very shrewdly suggests that the bruising of the abdominal wall may be due to external manipulations, and in favour of this is the rareness of bruising in tubal rupture.

I must thank Mr. Goodwin for his solicitude on my behalf because of the onslaught of Prof. Blair Bell. Under any circumstances my reverence of you, the knowledge that THE LANCET is on the desks of Editors of Standing throughout the world, and, above all, a sense of humour curb me from giving "reins and spurs to my free speech." I know Prof. Blair Bell does not believe a word I write, but he does not believe anybody very readily, and however forcibly he may express himself such a controversalist does stimulate even if he may cause a little pain.

In fairness to Prof. Blair Bell it must be pointed observations, as by others, these properties are shown to have a valuable clinical application, and yet, it seems, the significance of their clinical results may be perverted, an explanation being substituted for which there is no experimental basis. I submit that chemical methods of combating infection should be based on accurate knowledge of the capabilities of the agent used for destroying the particular micro-organism concerned; if they remain, as they largely are now, a matter of personal taste, or of conventions dating from the past, the only prospect of improvement is by the process of trial and error, one which in therapeutics may be almost indefinitely prolonged.

I am, Sir, yours faithfully,

LAWRENCE P. GARROD.

Pathological Department, St. Bartholomew's Hospital, London, E.C., Feb. 8th, 1932.

THE PREVENTION OF DEAFNESS.

To the Editor of THE LANCET.

SIR,—In your issue of Jan. 30th, Mr. Macleod Yearsley takes me to task for a sweeping condemnation of the Zünd-Burguet and similar apparatus for re-education of the deaf. In so far as the statement was not made on personal experience I stand corrected. But, in making it, I was guided not only by the general attitude on the subject, but also by the personal experience of two friends who had tried the method as patients. Both of them are highly educated people, one a most observant medical practitioner. I am only too pleased to learn that their unsatisfactory experience is not universal, and I am obliged to Mr. Yearsley for drawing my attention to his handbook on the subject.

I am glad that Mr. Yearsley should regard me as a follower of himself and Dr. Kerr Love in preaching the prevention of deafness. Their pioneer work is widely known, if not suitably recognised. All who have the welfare of the deaf and the potentially deaf at heart know the vast difference that their work has made.

I am, Sir, yours faithfully,

Harley-street, W., Feb. 8th, 1932. MAURICE SORSBY.

THE ZÜND-BURGUET METHOD IN VERTIGO.

To the Editor of THE LANCET.

SIR,—It is encouraging to those who know and appreciate M. Zünd-Burguet and his method to find that the value of the Electrophonoïd is becoming more and more recognised in this country. I would like to endorse Mr. J. A. Keen's outspoken article on its use in the Ménière syndrome. Its value in the treatment of vertigo is pointed out in my *Manual* (written in collaboration with M. Zünd-Burguet and published in 1927) and I contributed a striking case in support of this in the *Practitioner*, in 1927. It may interest your readers and Mr. Keen if I briefly condense the main facts of this observation here.

Miss A.B., 21, became deaf in the left ear following an attack of acute middle-ear catarrh two to three years earlier. For two years she had suffered with increasing vertigo and underwent several time-honoured treatments without result. At the time she consulted me the vertigo had become so severe, causing her to fall to the right, that she feared to go out. The whisper hearing was reduced in the left ear to 2 feet. Romberg's test showed unsteadiness to the right. No nystagmus. No tinnitus. Electrophonoïd treatment was begun and the vertigo ceased before 15 sittings had been completed. It has never returned. At the end of 30 sittings the hearing was 12 feet. She had a later consolidating course o 20 sittings and the hearing increased to 15 feet This highly satisfactory result has been maintaine to the present date, and for three years she has bee an enthusiastic mountaineer.

Since this case I have had three Ménière patient in all of whom the vertigo has speedily disappeare under the electrophonoïd treatment.

I am, Sir, yours faithfully,

MACLEOD YEARSLEY.

Harley-street, W., Feb. 6th, 1932.

METEOROLOGICAL FACTORS ON HEALTH.

To the Editor of THE LANCET.

SIR,—In the paper reported in your issue Jan. 30th, the Director of the Meteorological Offic Dr. Simpson, concluded that the only recognisabl influence of meteorological conditions on huma health was the stimulation produced by the coolin effect of wind. How far we have travelled since joined the profession, when the fevers and oth disorders we met abroad were commonly ascrib to climate! Against that belief I always protested it was so hopeless, discouraging all effort towards t prevention of disease. In a man-of-war one cou get observations registering the meteorological cond tions every four hours day and night. These recorded regularly, and luckily we spent most three winters in Malta harbour. At first one cou come to no conclusions, but in 1887–88 and 1888– it appeared that if at any hour of the day a relati humidity of 80 per cent. was recorded, a case of so throat came for treatment the following mornin two coincident observations, meteorological and nos logical. For years afterwards I kept logs for t Meteorological Office, who sometimes were go enough to lend me instruments, and besides ma observations at other times for myself, but nev obtained further coincidences of value. Those mention from Malta, were made in a central-batte ship, without artificial ventilation, with some 650 me Whether the humidity caused the disease, wheth it was a measure of the *stillness* of the air in t thermometer screen, and so related with the pover of ventilation in the ship below, I cannot say; the coincidence did occur, there, and I have nev since spent time in a harbour so airless, in so lar a ship.

When I came home I sought for similar reco of observations, and only found them in the "Pract of Medicine" of Dr. Aitken, then professor of medici at Netley, who quoted them from Dr. Francis Hon surgeon to Cadogan's (6th) Dragoons, at Bois-le-D in Flanders, in 1748. He thought humidity a pri cause of disease, which attacked especially troops damp situations. He had a hydrometer, catg From June 29th to July 12th, dry weather, "no m taken bad." On the 12th, "my hydrometer fell ve low," the distemper began; three men were seiz with it, and others every day in the next week whi continued damp; there were not so many in t dryer weather that followed, and so on.[1] I have personal interest in these inconclusive observatio made as they were by my great-grandfather, and have been unable to find others definitely paralleli meteorological observations with the incidence disease.

As was remarked in the discussion on Dr. Simpso paper, often empiricism comes by its own in the lo run. We all feel the benefit of a bright dry da methods. Patience, unfailing kindliness, the faculty of always realising and understanding another man's point of view, combined with practical demonstration and help, quickly convinced an ever-increasing number of dairy farmers round Reading that the application of science was not a fantastic folly, but a saving of hard cash as their milk kept longer. From these beginnings he followed the milk through its various stages to the time it was delivered to the consumer. The retailers were quickly convinced that scientific methods were a practical and money-saving proposition.

---

[1] Home, F.: Medical Facts and Experiments, London, 17 pp. 61 and 62.

"The ideal Williams aimed at was to free, in time, the country of bovine tuberculosis, so that fresh milk could be safely drunk. There was no doubt in his mind that there are properties in raw milk that are destroyed by heating, and he bewailed the fact that practical research on these properties has been so neglected. His loyalty and devotion to his staff was only equalled by theirs to him. He refused absolutely to take any credit to himself for work done by others, and insisted on each one having his share, including the laboratory assistants. On the other hand, not a particle of work was allowed to be published that could not stand up to any criticism directed against it. He had a great sense of humour and a charming twinkle in his eye which endeared him to his friends, children, and animals. If anyone was in trouble of any kind he would never spare himself or his pocket to do what he could to help. His health, never robust, was seriously affected by a gastric operation some years ago, and by constant lecturing all over the British Isles he overdid his strength. Latterly he had been terribly worried by the reduction in the salaries of his staff and the constant strain of obtaining enough money to carry on the Institute."

It remains to put on record Dr. Williams's love of nature in all its moods which led him to find his chief recreation in climbing, and no doubt influenced him in giving up an academic career in Liverpool for one more in contact with animals and growing things.

While in Liverpool he married Helena Margaret, daughter of Thomas Crosfield, and he leaves two sons and a daughter.

THE LATE COLONEL S. F. LOUGHEED, R.A.M.C.

Major-General Edgar M. Pilcher writes: Will you allow me space for a few grateful and appreciative words to the memory of Colonel S. F. Lougheed, of the Royal Army Medical Corps, whose death was announced last week? Lougheed was prevented by chronic and persistent ill-health from rising to the top of his service, but he was one of those whose spirit triumphs over the frail body, and to a small band of workers, of whom I am proud to have been one, he was a perpetual inspiration. Invalided from India in 1894, he wasted no time in self pity or futile search for amusement, but set himself to a course of post-graduate study at the West London Hospital, and found the work most suited to his taste in the surgical clinic of the late Mr. Leonard Bidwell. Lougheed had beautiful hands and a real flair for surgery, and when his appointment to the Royal Arsenal at Woolwich gave him opportunity to practise he showed that he could not only operate but teach. Those of us who came within the range of his influence will bear me out when I say that surgery in the Army, gradually arising from a very dark age, took much of its inspiration from the enthusiasm and personal example of Samuel Lougheed.

PARLIAMENT

NOTES ON CURRENT TOPICS.

GOVERNMENT'S TARIFF POLICY.

On Thursday, Feb. 4th, the House of Commons went into Committee of Ways and Means (Sir D. HERBERT, Chairman of Committees, in the chair) on the first of a series of resolutions connected with the Government's Trade Bill.

Mr. NEVILLE CHAMBERLAIN, Chancellor of the Exchequer, in moving the resolution, said that, so far, the Government had averted disaster to the country; now they were beginning constructive work. They had succeeded at least in improving the situation since last November. The emergency Budget might have been thought unrealisable, but, while he could not guarantee final results at that stage, the collection of income-tax was 50 per cent. higher than last year, and, if companies followed the magnificent lead of individual taxpayers, the yield would more than compensate for losses on other taxes. The cost of living had been unaffected by the fall in the external value of the pound sterling, and was actually six points lower than on Jan. 1st, 1931. Sterling, too, had shown gratifying stability. There had also been a definite improvement in trade in certain directions.

There was no use, however, in pretending that the country had turned the corner. Apart from other important considerations, the trade balance was still adverse. Taxpayers could not be heroes indefinitely; taxation could not remain indefinitely at a crippling level. A credit balance of trade of £100,000,000 in 1929 had become an adverse balance of £113,000,000 in 1931. The problem was to increase exports and to diminish imports. A policy must be chosen which offered the greatest balance of advantages over disadvantages. The scheme chosen had seven objects: (1) the correction of the balance of trade; (2) the raising of revenue without imposing undue burdens on any section of the community; (3) moderate and scientific protection to transfer production to our own fields and factories; (4) encouragement of industrial efficiency; (5) promotion of tariff agreements with foreign countries; (6) retaliation against foreign tariff discrimination; (7) advancement of Imperial economic partnership. The basis of the scheme was a general tariff of 10 per cent. modified by a short free list, which included wheat, meat, fresh fish of British taking, raw cotton and wool, and tea. The 10 per cent. would not be added to existing duties and existing Acts imposing them would continue until replaced by something else. Neither the new general, nor the new specific duties, would apply to goods from the Dominions, at least pending the results of the Ottawa Conference. All produce from colonies, protectorates, or mandated territories would also be exempt. If any foreign countries discriminated against British goods the Board of Trade would have power to impose duties up to 100 per cent. on their goods. After the Ottawa Conference there would also be power to offer reciprocal lowering of tariff barriers to foreign countries.

After considerable discussion the debate on the first resolution was adjourned.

HOUSE OF COMMONS.

WEDNESDAY, FEB. 3RD.

Street Accidents.

Mr. BUCHAN-HEPBURN asked the Home Secretary whether he could give any information, in advance of the annual return which was presented to Parliament, of the number of street accidents caused by vehicles and horses in 1931, which resulted in personal injury and came to the notice of the police.—Sir H. SAMUEL replied: The following are preliminary figures as to street accidents caused by vehicles and horses during 1931, which resulted in personal injury, out that Cullen preserved the tube in his patient with a tubal pregnancy. In my patient there was active bleeding, the tube was ruptured, and the peritoneal cavity was sufficiently full of blood to cause abdominal distension and moveable dullness in both flanks.—I am, Sir, yours faithfully,

W. E. TANNER.

Queen Anne-street, W., Feb. 6th, 1932.

To the Editor of THE LANCET.

SIR,—I should like first to express my regret that Prof. Blair Bell should have misconstrued the meaning of the opening paragraph of my letter. No one reads his articles with greater interest than I; there is a refreshing originality about them, and they open new avenues of thought as well as giving many useful suggestions about treatment, though they necessarily must be controversial at times. It is to this very originality that I was trying to pay compliment.

I think he is a little hard on Mr. Tanner, when one considers that he did not see the specimen or the condition of the abdomen when it was opened. Surely, if Mr. Tanner says that the abdomen was filled with blood, it must have been. This is not an uncommon sight in London, but perhaps our women bleed more freely than they do elsewhere. I think he must be congratulated on having adopted the quickest surgical procedure consistent with safety in this case.

My "elementary" questions were asked in the hope that I might learn something which might help me in the future, but the answers to them, and the bibliography referred to in the text of Prof. Blair Bell's letter, leave me what I was when I first wrote—an unregenerate gynæcologist.

I am, Sir, yours faithfully,

AUBREY GOODWIN.

Queen Anne-street, W., Feb. 6th, 1932.

To the Editor of THE LANCET.

SIR,—In your issue of Jan. 16th, Mr. W. E. Tanner reported a case of ruptured tubal gestation with bruising in the umbilicus and on the abdominal wall, and remarked that he could not find a record of any similar case. The bruising and discoloration of the umbilicus and skin of the anterior abdominal wall was described by Cullen several years ago, and is known in this country as "Cullen's sign." Any free bleeding in the peritoneal cavity may give rise to this sign, hence it is not pathognomonic of ruptured tubal pregnancy. I, personally, have only seen it once in a large number of cases of ruptured ectopic gestation.—I am, Sir, yours faithfully,

A. J. GORDON, M.D., F.A.C.S.,
Associate Attending Gynæcologist, Newark City Hospital.

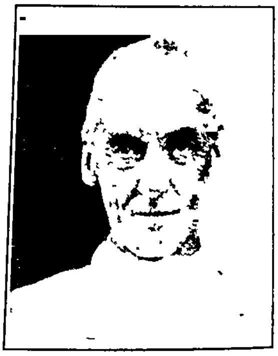
Feb. 2nd, 1932.

COST OF MOTOR ACCIDENTS TO HOSPITALS.—Last year 50 road accidents were admitted to the Horton General Hospital, Banbury, as compared with 26 in 1930. Of these accidents 27 were to riders of motor-cycles. It was stated at the annual meeting that two cases cost over £300. The East Suffolk and Ipswich Hospital last year admitted 109 motor-accident patients, who stayed for an aggregate of 3155 days. The average stay of an in-patient in this institution is slightly under 19 days, but these averaged 30 days. They cost £1419, and £136 was recovered from the insurance companies; the patients gave £92. Analysis of the cases shows that 12 were motor-car drivers and passengers, 36 motor-cyclists and pillion-riders, and 61 pedestrians. It is pointed out that the Road Traffic Act makes no provision for subsequent treatment in the out-patient and special departments, nor for the cost of transport, which at Ipswich exceeded £38.

OBITUARY

ROBERT STENHOUSE WILLIAMS,
M.B., B.Sc. Edin., D.P.H. Camb.

Dr. Stenhouse Williams, Director of the National Institute for Research in Dairying at Reading, died on Feb. 2nd in University College Hospital, London, where he was taken unconscious after an apoplectic seizure on the Irish mail train. He was in his sixty-first year and, although obviously frail, was carrying on his work at full pressure until the previous day. His death removes a remarkable personality, and one which achieved much by devotion to a cause—namely, the production of clean milk.



DR. STENHOUSE WILLIAMS.

Dr. Williams was born and brought up in Liverpool, commencing his medical study there and completing it in Edinburgh, where he qualified in 1896 and took the higher degrees in 1902. He then returned to Liverpool as assistant superintendent of the Institute of Comparative Pathology, later becoming bacteriologist to the David Lewis Northern Hospital, and lecturer on public health bacteriology in the University. For some years he was assistant physician to the Stanley Hospital and to the Hospital for Consumption, and at various times he held a number of teaching appointments and contributed freely to the literature of experimental and clinical pathology. In 1912 he was called to Shinfield, near Reading, to direct the research institute founded by the Ministry of Agriculture and Fisheries, and governed by a board representing the Ministries of Health and Agriculture, as well as the organised farming and dairying associations. For 20 years he directed this Institute with its five departments of bacteriology, chemistry, husbandry, physiology, and dairying, with the aid of a band of workers who were in course of time drawn into the University of Reading, Dr. Williams himself being given the chair of research in dairy bacteriology. An account of his work may be given in the words of one of his close associates, Dr. E. C. G. Maddock, honorary research fellow. Dr. Maddock writes:—

"Stenhouse Williams may be called the founder of the Clean Milk Movement in this country. From the very beginning he realised that the Ministries of Health and Agriculture must work together to this end, and he was always loyally helped by members of the veterinary profession, who responded to his enthusiasm. With his natural thoroughness he decided that for milk to be delivered clean the process must begin with the cow and the milker, and be on such a practical basis that it could be followed by the ordinary dairy farmer. At Shinfield he began work in the old farm cowshed, and by expending only five pounds on concrete floors, efficient lighting, drainage, and ventilation, demonstrated that clean milk could be produced through the hottest weather as long as the cows and milkers were clean and the vessels used were sterilised. Critics said it was impossible to get the dairy farmers to follow his

Cancer among Welsh Nickel Workers.

Mr. DAVID GRENFELL asked the Home Secretary whether he had received notification of the deaths from cancer among men employed at the Mond Nickel works at Clydach, near Swansea, and the number of deaths from this cause during the last three years among men who had been employed at these works prior to their disablement.—Sir H. SAMUEL replied: Notification under the Factory Act is required only in the case of cancerous ulceration of the skin due to tar, pitch, or certain other substances. No cases of this form of cancer have been notified from the works in question, and I am informed that, so far as the Factory Department is aware, there is no process carried on at the works which would expose the workers to this risk. At the request of the Department the Medical Officer of the Company has gone through their records, and finds that during the last three years six men who had been employed at the works died from cancer, but there does not appear to be any ground in any of these cases for connecting the disease with the employment. The average number of men employed during the three years was 1105. The average age of death in the six cases was 53.

Mr. GRENFELL asked if the figures given were not indicative of a very high rate of cancerous deaths, especially in view of the form of cancer which attacked all these people, which was the same kind in each case.

Sir H. SAMUEL: No. I am informed that the number of deaths is not disproportionate to that in the population generally, nor do any particular cases show symptoms of the particular kind of cancer which is due to industrial disease.

Mr. GRENFELL asked the right hon. gentleman to keep a watchful eye on the subject, and to keep as accurate a record as possible of the number of cancerous cases at these works.

Sir H. SAMUEL said that very full and careful inquiries had been made. If Mr. Grenfell would give him information which would show that these cases—six in the last three years out of 1100 workmen—were due in any degree to their employment he would be most happy to look into the matter.

Continental Vegetables and Foot-and-mouth Disease.

Major CARVER asked the Minister of Agriculture if his department had investigated the possibility of foot-and-mouth disease in this country being due to the importation of Continental vegetables; and, if so, what was the result of such investigation.—Sir J. GILMOUR replied: Inquiries are made into the source of infection in every outbreak of foot-and-mouth disease. While it is of course possible that the disease may be introduced by imports of vegetables, or of other commodities, *in no case has it been established that* infection was definitely attributable to the importation of Continental vegetables, and no evidence has yet been forthcoming which would justify the prohibition of such imports on these grounds.

Lieut.-Colonel FREMANTLE asked whether this subject had been referred to the newly constituted Agricultural Research Committee.

Sir J. GILMOUR said that very definite inquiries were always going on into foot-and-mouth disease.

Milk for School-children.

Mr. MCENTEE asked the President of the Board of Education how many local education authorities were providing milk for school-children, excluding National Milk Publicity Council schemes; and the number of children supplied with milk through the National Milk Publicity Council schemes at the latest convenient date.—Mr. RAMSBOTHAM, Parliamentary Secretary to the Board of Education, replied: During the week ending Jan. 23rd last, 81 local education authorities in England and Wales were providing milk for school-children under Sections 82 and 85 of the Education Act, 1921. My right hon. friend understands from the National Milk Publicity Council that about 800,000 children are receiving milk under their schemes.

Local Authorities and Slum Clearance.

Dr. SALTER asked the Minister of Health the number of local authorities in England and Wales who had submitted clearance orders for confirmation under the Housing Act, 1930; the number of such clearance orders that had been actually confirmed by him at this date; and the number of houses and other buildings which would be demolished as a consequence of such clearance orders.—Mr. E. BROWN replied: Up to Jan. 31st last 51 local authorities in England and Wales had submitted clearance orders under the Housing Act, 1930, for areas containing 3681 houses, and 44 clearance orders had been confirmed.

MEDICAL NEWS

Royal Colleges of Physicians of London and Surgeons of England.

At the Final Examination of the Conjoint Board held from Jan. 11th to Feb. 3rd the following candidates were approved in the subjects indicated, but are not yet eligible for diplomas:—

Medicine.—A. L. Abeyewardene, L.M.S. Ceylon, Univ. Coll.; P. Baron, M.B. Cape Town; G. P. Barua, M.B. Calcutta, London; C. G. Batty-Smith, Camb. and St. George's; S. J. Bellgard, L.M.S.S.A. Lond., St. Mary's; F. C. Bourgault du Coudray, London; M. J. Brookes, London; J. D. Burrows, St. Thomas's; T. Chadderton, Manchester; N. C. Coombs, Camb. and Bristol; D. R. Crabb, St. Bart.'s; J. M. Cribb, Cardiff; W. H. D. Davies, St. Bart.'s; Mary T. Day, Charing Cross; H. De, St. George's; L. Dexter, St. Bart.'s; G. E. Dunkerley, Univ. Coll.; W. G. Evans, Camb. and St. Mary's; K. Fawssett, St. Thomas's; Catherine F. Forrest, Royal Free; A. E. Francis, St. Bart.'s; R. G. Gilbert, St. Bart.'s; J. A. S. Goonawardena, L.M.S. Ceylon, Univ. Coll.; R. J. C. Hamilton, St. George's; O. C. Hamilton-Jones, Liverpool; G. R. Hargreaves, *Univ. Coll.*; F. R. Hayward, Guy's; J. S. Horsley, London; A. D. Iliff, St. Bart.'s; D. H. Irish, Guy's; L. S. Jaikaran, London; R. James, St. Mary's; T. B. Jones, Westminster; Agnes V. Kelynack, Royal Free; R. Kempthorne, Oxf. and Univ. Coll.; R. Knox, Oxf. and St. Bart.'s; R. A. Manclark, Middlesex; J. de C. Muller, St. *Thomas's*; W. Mushin, London; K. H. Nassif, Royal Free; H. E. Offord, St. George's; G. B. Palmer, L.D.S. Eng., Guy's; O. R. L. L. Plunkett, St. George's; S. Rameshwer, M.B. Lucknow; A. Rashid, West London; H. M. Rashid, Birmingham; S. R. H. Razwi, London; L. J. Richmond, M.B. Leeds; D. F. Robb, St. Thomas's; G. C. Sawyer, Guy's; B. H. Sayed, M.B. Punjab, St. George's; E. F. Scowen, St. Bart.'s; E. J. Somerset, King's Coll.; Charlotte M. H. Sparrow, Royal Free; J. W. C. Symonds, St. Bart.'s; J. R. Thornton, St. Thomas's; J. B. L. Tombleson, St. Thomas's; C. M. Vaillant, Oxf. and Liverpool; E. J. Walsham, St. Thomas's; E. W. Wilkins, Birmingham; V. F. F. Winslow, St. Bart.'s; S. W. Wright, Guy's; and M. Zinober, Cape Town.

Surgery.—S. D. Ahuja, M.B. Punjab, Charing Cross; J. C. G. Anderton, Camb. and Westminster; S. T. Anning, Camb. and Leeds; H. J. B. Atkins, B.A. Oxf. and Guy's; C. G. Barnes, St. Mary's; J. R. Blackburne, St. Bart.'s; R. W. W. Bose, Camb. and London; H. W. L. Broadbent, Camb. and St. Mary's; G. H. Brookman, St. Bart.'s; J. Cann, Camb. and St. Thomas's; D. B. Cater, Camb. and Charing Cross; I. A. Cathie, Guy's; A. H. Chenard de la Giraudais, Charing Cross; S. J. Chesser, Camb. and St. Thomas's; N. G. Chitnis, Bombay and Dublin; C. A. Clarke, Camb. and Guy's; Gwendolen N. Cook, Royal Free; P. T. Cooper, Camb. and St. George's; F. N. Corfe, L.D.S. Eng., Guy's; A. G. Cowie, St. Mary's; G. W. Crimmin, Camb. and St. Thomas's; P. N. Cutner, M.B. Edin.; J. E. Davenport, Camb. and London; A. M. Davies, Bristol; J. Davies, London; E. A. Devenish, Univ. Coll.; L. W. B. Dobbin, Camb. and London; G. M. Evans, Bristol; Q. F. Evans, St. Thomas's; W. B. Evans, Camb. and St. Bart.'s; J. H. Fisher, Camb. and London; J. F. P. Forster, Birmingham; M. Fröhlich, Middlesex; W. H. Gabb, Camb. and St. Bart.'s; G. D. Galwankar, Bombay; G. H. Gibbens, St. Thomas's; K. J. Gilchrist, Guy's; W. G. Gill, Camb. and Guy's; A. J. Grace, Guy's; L. Greenfield, London; C. S. Hall-Smith, Camb. and St. Bart.'s; J. Halperin, St. Bart.'s; J. C. Hardy, Univ. Coll.; E. R. Hargreaves, Camb. and St. Mary's; C. L. Hay-Shunker, St. Bart.'s; R. A. P. Hogbin, Guy's; M. D. C. Hosford, St. Bart.'s; Ursula Y. im Thurn, Univ. Coll.; C. G. Jones, Middlesex; T. B. Jones, Camb. and St. Thomas's; W. W. Jones, Guy's; R. Kempthorne, Oxf. and Univ. Coll.; W. Kravchick, St. Bart.'s; C. B. Lanyon, Univ. Coll.; A. R. R. Le Fleming, Camb. and St. Thomas's; A. W. D. Leishman, Oxf. and St. Bart.'s; A. A. Lewis, Guy's; P. Lewis, Leeds; J. L. Lovibond, Camb. and Middlesex; D. C. McClure, London; D. B. McGavin, M.B. Camb., St. Bart.'s; M. B. McGinn, London; Mary A. McKean, Royal Free; S. O. Massey, Middlesex; F. S. A. Maw, Camb. and King's Coll.; A. R. R. Mears, Camb. and St. Bart.'s; R. V. F. Mercer, Camb. and St. Bart.'s; J. A. W. Miller, Guy's; T. D. F. Money, Camb. and St. Thomas's; W. H. W. Morris, St. Thomas's; Alice M. Naish, Camb. and Royal Free; W. T. North, Guy's; J. A. Nunn, Oxf. and St. Bart.'s; J. Parkes, Camb. and St. Thomas's; R. V. Payne, Camb. and Guy's; R. E. J. Pembrey, St. Thomas's; S. H. B. Platts, Camb. and Leeds; C. B. R. Pollock, Guy's; V. T. Powell, Cardiff; J. C. Read, L.D.S. Eng., Guy's; R. G. Reid, Guy's; J. P. Reidy, Camb. and London; L. O. Roberts, St. Bart.'s; M. L. Rosenheim, Camb. and Univ. Coll.; A. Rothwell, Camb. and King's Coll.; M. H. P. Sayers, St. Thomas's; B. Shanovitch, London; I. Singh, M.B. Punjab, London; F. J. Sladen, Middlesex; S. B. Smith, Guy's; J. R. Strong, St. Bart.'s; Annie C. Taylor, Camb. and Univ. Coll.; E. H. Thierry, Univ. Coll.; C. W. Thomas, Camb. and St. Thomas's; A. S. Thorley, Univ. Coll.; H. A. Treble, Oxf. and Guy's; J. T. Turner, Camb. and St. Thomas's; J. M. Vaizey, Camb. and London; O. J. Vaughan-Jackson, Oxf. and London; A. R. Walters, Middlesex; C. B. M. Warren, Camb. and St. Bart.'s; Phyllis E. Watson, Camb. and Charing Cross; G. D. Wedd, Camb. and St. Bart.'s; H. D. White, Camb. and St. Bart.'s; H. M. Williams, St. Bart.'s; A. L. Winner, Univ. Coll.; T. G. R. Woods, St. Bart.'s; H. W. Wykes, Middlesex; and M. Zinober, Cape Town.

Midwifery.—A. L. Abeyewardene, L.M.S. Ceylon, Univ. Coll.; E. H. Allen, St. George's; S. T. Anning, Camb. and Leeds; K. S. Ayyar, M.B. Madras, Middlesex; C. G. Baker, and came to the notice of the police:—The total number of such accidents recorded in Great Britain was 181,486, of which 6495 resulted in fatal injuries to one or more persons. The corresponding figures in 1930 were 156,793 and 7074 respectively. The number of persons killed in 1931 was 6685 and 202,147 injured, as against 7305 and 177,895 respectively in 1930. There was thus in 1931 a considerable increase in the total number of accidents resulting in personal injury which were recorded by the police, but a decrease in the number of fatal accidents as compared with 1930. The figures for England and Wales show similar changes, the total number of accidents resulting in personal injury being 165,521 (an increase of 23,127), and fatal accidents 5851 (a decrease of 466). The total number of persons killed or injured in England or Wales was in 1931 190,831 (an increase of 22,329), and the number killed 6026 (a decrease of 496). These changes in the number of persons killed and injured respectively suggest that the increase in the total number of accidents resulting in personal injury may be more apparent than real, and attributable to the police obtaining fuller information regarding the accidents which occur by reason of the institution of the motor patrols and the new requirements of the road traffic Act as to the reporting of accidents. The figures from many police districts support this view, but it is to be noted on the other hand that those for the metropolitan police district show a decrease in the total number of persons injured, as well as a decrease in the number killed, the totals for 1931 being 1324 killed and 54,422 injured (not fatally), as against 1398 and 55,827 respectively in 1930. On the other hand, in some police districts, including, for instance, parts of Kent and the West Riding of Yorkshire policed by the county police, there was an increase in 1931 in the number of persons killed as well as in the number of persons injured. Amongst the cities and boroughs in England and Wales, Birmingham had the highest total of killed or injured during 1931—namely, 5688, an increase of nearly 800 over the previous year. This figure, however, is exceeded by Glasgow, where the number of persons killed or injured was 5904, which is, however, nearly 300 less than in 1930. The Liverpool figures show an increase in persons killed or injured from 4447 to 4648, and those for Manchester an increase from 3571 to 3848. Wales, as a whole, had a total of 232 killed and 7422 injured, as compared with 270 killed and 5816 injured during 1930. In Scotland the corresponding totals show a decrease of 124 killed and an increase of 1427 injured, the totals for 1931 being 659 and 17,342 respectively.

Rates of Relief.

Mr. Albery asked the Minister of Health what steps had been taken to prevent differentiation in the rates of relief paid in areas where similar conditions prevail.—Sir E. Hilton Young replied: The amount of relief to be afforded is for the decision of the public assistance authority in the light of the ascertained needs of the individual case. I have no power either to require uniformity or to define what, for the purpose of assessing relief, are similar conditions. As regards the area to which my hon. friend called my attention in an earlier question, I am informed that the local authority have taken action to remove the difficulty to which he referred.

Maternal Mortality.

Mr. McEntee asked the Minister of Health when the publication of the report of the departmental committee on maternal mortality might be expected.—Sir E. Hilton Young replied: The interim report of this committee was published 18 months ago. I have not yet received any further report, but I understand that the committee hope to present their final report very shortly.

Rural Housing.

Mr. Hurd asked the Minister of Health the number of rural district councils in England and Wales who made applications for special Exchequer assistance under the provisions of the Housing (Rural Authorities) Act, 1931; the total number of houses included in their proposals; and the number of houses which the Central Advisory Committee had recommended for erection under this Act.—Sir E. Hilton Young replied: Applications have been received from 145 rural district councils of which six were subsequently withdrawn. The remaining 139 applications were in respect of 6735 houses. The committee are not yet in a position to make actual recommendations. They have informed 97 authorities that they are prepared to entertain applications to the extent of 1591 houses for the agricultural population.

Pensions for Nurses.

Dr. O'Donovan asked the Minister of Health if he was able to give the details of existing arrangements for the interchangeability of pension schemes for nurses, sisters, and matrons in municipal hospitals; and if he would be prepared to coördinate the nurses' pension schemes in federated voluntary hospitals and in municipal hospitals.—Sir E. Hilton Young replied: I would refer my hon. friend to the provisions of the Local Government and Othe Officers' Superannuation Act, 1922, and particularly t Section 8 and 16 of that Act. I am, as my predecessor have been, willing to consider any practicable proposal o the lines mentioned in the second part of the question, bu no such scheme has as yet been submitted.

MONDAY, FEB. 8TH.

London Tube Workers and Asbestosis.

Dr. O'Donovan asked the Home Secretary if he wa advised that the precautions taken to prevent fatal lun disease in workers lining London tubes with asbestos wer adequate.—Sir Herbert Samuel replied: I have n powers of control in respect of this work under the Factor or other Acts, and have no information at present as to th precautions taken. I will make inquiries, however.

G.M.C. and Indian Medical Degrees.

Mr. Thomas Griffiths asked the Secretary of State f India what was the present position in regard to the reco nition by the British Medical Council of degrees granted b the faculties of medicine in Indian universities; and wh stage had been reached in the setting up in India of a Indian Medical Council.—Sir S. Hoare replied: T conditional recognition accorded by the General Medic Council to the medical degrees of certain Indian universiti was withdrawn in March, 1930. A revised draft Bill for t establishment of an All India Medical Council has be prepared, and it is hoped to introduce it in the Indi Legislative Assembly at an early date.

Importation of Boneless Meat.

Lord Scone asked the Minister of Health if he wou consider the advisability of prohibiting the importati of boneless meat, in view of the difficulty of detecti unsoundness or disease in such meat.—Mr. Ernest Bro (Parliamentary Secretary to the Ministry of Health) replie The importation of boneless meat which affords insufficie means of identification with definite parts of a carcass prohibited under the Imported Food Regulations of 19 My right hon. friend is now considering the amendment these regulations so as to require a recognised offic certificate of the country of origin with all imports of fre meat less than the whole carcass.

TUESDAY, FEB. 9TH.

Boys Working Underground at Night.

Mr. Tinker asked the Secretary for Mines if he had c sidered the request from the Miners' Federation of Gr Britain to meet them to discuss the position of boys un the age of 16 years working underground on night shi and if he was prepared to meet them.—Mr. Isaac F replied: The answer to both parts of the question is in affirmative.

Safety in Mines.

Mr. Tinker asked the Secretary for Mines how ma safety-in-mines conferences had been held; was it his int tion to have the proceedings and subjects that were cussed published and available to mine workers; and it was his intention to hold similar conferences.—Mr. Isa Foot replied: The sixth district Safety Conference was h at Nottingham last Saturday, and was attended by so 4000 persons representative of all interests in the min industry. I intend to hold another conference at Swan in March, and the eighth and final conference probably Birmingham in April. Every mining area in the coun will then have been covered. The proceedings at th conferences are well reported in the local press; and material is used in the various safety publications of department, and in the lectures and demonstrations o smaller scale by which the work of these large conferen is being followed up.

Sunday Repairs to Telephones.

Mr. Hutchison asked the Postmaster-General wheth in view of the fact that no telephone repairs were car out between 1 P.M. on Saturday and Monday morni except in the case of those telephones belonging to doct this privilege could be extended to the general pub seeing that no money was refunded in respect of the per in which their telephones were out of working order Mr. White, Assistant Postmaster-General, replied: T present arrangements for fault repair during week-e apply not only to the circuits of doctors, but also to alarm, police, hospital, and other circuits where the imm diate restoration of communication is in the general pub interest. My right hon. friend is considering whether is possible to extend their scope.

Hunterian Society.

The Hunterian Oration will be delivered by Dr. J. B. Christopherson at the Apothecaries' Hall, Water-lane, London, E.C., at 9 P.M. on Thursday, Feb. 25th. His subject will be the Ætiology of Chronic Bronchitis.

Royal Statistical Society.

Prof. Major Greenwood, F.R.S., will give an address to this society at 5.15 P.M. on Tuesday, Feb. 16th, in the hall of the Royal Society of Arts, John-street, Adelphi, London, W.C. His subject is the Quantity and Quality of Official Statistical Publications.

The Marie Curie Hospital.

The first endowed bed at this hospital was dedicated last week by the Bishop of Exeter, representing the women of Devon who have subscribed £2000 for the purpose. The first occupant came from Plymouth, the bed being intended for the free treatment of Devonshire women.

Subscription Benefits at King's College Hospital.

At a dinner in aid of this hospital last week Lord Gorell explained a scheme for attracting new subscribers. A subscription of £1 by a single person, £1 10*s*. by a married couple, and £2 by married persons with children will give the right during the year to three weeks' in-patient maintenance and treatment.

London School of Hygiene and Tropical Medicine

The Langley prize, which is usually awarded every three years for the best paper submitted by officers of the West African Medical Service—whether on the active or retired list—has been awarded by the School in equal shares to Dr. E. C. Smith, for his paper, A Dermatological Atlas of Nigeria, and Dr. Hope Gill, for his paper on Diagnostic Methods in Human Trypanosomiasis.

University of Durham College of Medicine.

The second of a series of lectures on Recent Advances in Physiology applicable to Medicine will be given at this College, Newcastle-upon-Tyne, at 4.45 P.M., on Friday, Feb. 19th. The lecturer will be Dr. J. J. R. Macleod, F.R.S., regius professor of physiology in the University of Aberdeen, and the subject Diabetes as a Physiological Problem. Medical practitioners are invited to attend.

Tuberculosis Association.

At a meeting of this association, to be held at Oxford from March 17th to 19th, the principal subjects of discussion will be Chronic Pulmonary Suppuration and its Treatment by Bronchoscopy and Drainage (Dr. A. S. Scott Pinchin and Dr. H. V. Morlock), Selective Lung Collapse in Bilateral Disease (Dr. F. Gravesen), and the Ætiology and Treatment of Spontaneous Pneumothorax (Dr. L. S. T. Burrell). The hon. secretary of the association is Dr. G. T. Hebert, of St. Thomas's Hospital, London, S.E. 1.

Royal Medical Benevolent Fund.

At the meeting held in January the committee voted 78 grants amounting to £1844. The following are particulars of a few cases helped:—

M.R.C.S., aged 62. One daughter aged 9. Applicant had to retire in 1929. He is suffering from chronic nephritis. He has had a number of cerebral attacks, culminating in a hæmorrhage which has caused paralysis. He can barely walk, and he is mentally incapable of any work. By the time he retired the practice had deteriorated and was unsaleable. The applicant and his wife are living on a pension of £87 10*s*. a year. The daughter's school fees have been arranged for. Fund voted £40 in four instalments, and other societies are being approached to coöperate with this case.

Widow, aged 53, of L.R.C.P. Husband died in 1927. The applicant suffers from cardiac condition and gall-stones, and is totally unfit for any employment. Her eldest daughter, aged 30, is paralysed and mentally affected, so that she requires constant care and attention. The youngest daughter is delicate. The son, aged 22, is a junior clerk. His salary is £80 a year, and he contributes £24 to assist his mother. The applicant's income is £90 a year. Fund voted £26, in four instalments, and will seek the help of other charities for this unfortunate family.

Widow, aged 67, of M.D. The applicant's husband was in receipt of an annuity of £40 from this Fund, and a Government pension which ceased at his death in 1932. The widow is left penniless. It is hoped that some reduced pension may be obtained from the Government for the widow. Fund voted £26 in four instalments.

Widow, aged 55, of L.S.A. Husband died after a few days' illness in November, 1931, at the age of 63. When the practice and house are disposed of, it is expected that there will be nothing left from the estate, for there is a mortgage to be paid off and debts to settle. There is a daughter, aged 14½. The only son, aged 30, a married man, is surgeon in one of H.M. Services stationed abroad, with a salary of £400 a year, and is at present allowing his mother £10 a month. Fund voted £26. The Ladies' Guild of the Royal Medical Benevolent Fund will assist in the education of the daughter.

Cheques should be made payable to the hon. treasurer of the Fund, 11, Chandos-street, Cavendish-square, London, W. 1.

Inquiry into Mental Deficiency.

The Minister of Health received a deputation on Feb. 9th from the County Councils Association, the Association of Municipal Corporations, and the Mental Hospitals Association on the subject of the sterilisation of mental deficients. They represented that while the associations for which they spoke had reached no final conclusion upon the desirability of sterilising mental deficients, they considered that the time had come at which a full inquiry should be made into the whole question. The Minister said that he agreed that there was a need for inquiry, and he proposed, as a first step, to arrange for inquiry to be made by competent persons into its scientific aspects.

Dentistry and National Health.

The Brighton and Hove Provident Dental Hospital has just removed to new quarters at 7, Buckingham-road, Brighton, and was formally opened on Feb. 5th by Sir Norman Bennett. After pointing out that the bearing which the teeth had on the general health had been increasingly appreciated of late years, Sir Norman said that what was wanted particularly now was some sort of service for adolescents between school-leaving age and the age at which they qualified for insurance benefits; for when children left school they got out of the habit of having their teeth regularly inspected. The present system of national dentistry might be summarised broadly as a fairly efficient, but lamentably weak, school service, a period of almost compulsory neglect, a further period of voluntary neglect, concluding with a short, intensive, and drastic course of treatment in middle or advanced age. Sir Norman expressed his sympathy with the hospital because it gave dental treatment to those who could not pay for it, or could only pay a little, and was prepared to give a similar service to wage-earners, with incomes below a certain limit, in return for weekly payments throughout the year under the Sussex Provident Scheme.

Appointments

BAND, D., M.B., Ch.B. Edin., F.R.C.S. Edin., has been appointed Assistant General Surgeon, Hospital for Diseases of Women, Edinburgh.

POOLER, H. E., M.B., Ch.B. St. And., Hon. Anæsthetist, Chesterfield Royal Hospital.

TAYLOR, DOROTHY M., M.B., Ch.B. Edin., Maternity and Child Welfare Officer, Sunderland Council.

THOMAS, OLIVER F., L.R.C.P. Lond., M.R.C.S., D.P.H., Tuberculosis Officer, Sunderland Council.

Births, Marriages, and Deaths

BIRTHS.

BEATSON.—On Feb. 2nd, at Grey Friars, Hutton Mount, Brentwood, Essex, the wife of Major B. Fraser Beatson, I.M.S. (ret.), of a son.

CAWTHORNE.—On Feb. 3rd, at Welbeck-street, W., the wife of Terence Cawthorne, F.R.C.S., of a son.

MARRIAGES.

TYLECOTE—PHYTHIAN.—On Feb. 6th, at Hitchin, Frank Edward Tylecote, M.D., F.R.C.P. Lond., Professor of Systematic Medicine in the University of Manchester, to Mable Phythian, Ph.D., late Warden of the Elvington Settlement, Kent.

DEATHS.

BROOK.—On Feb. 6th, at Mundesley, Norfolk, Samuel Stanley Brook, M.R.C.S., L.R.C.P., aged 46.

DAVIS.—On Feb. 4th, in a nursing home, London, Arthur Randall Davis, M.R.C.S., of Oaklands, Hythe, in his 77th year.

LILLIES.—On Feb. 5th, at Ashley-gardens, S.W., Arthur Chudleigh Lillies, son of the late George William Lillies, M.D., aged 73.

RAINSFORD.—On Feb. 4th, at Oak Lodge, Rolle-road, Exmouth, Colonel W. J. R. Rainsford, C.I.E., L.R.C.P.I., F.R.C.S.I., aged 80 years.

REBOUL.—On Feb. 4th, at Cannes, very suddenly, Dr. A. E. Reboul, L.R.C.P. Edin., M.D. Mont., of Châtelguyon and Cannes, aged 58.

SINCLAIR.—Suddenly on board M.V. *Reina del Pacifico*, Thomas Walker Sinclair, M.D., D.P.H., late Medical Officer of Health, Melbourne, Australia.

WILLIAMS.—On Feb. 2nd, very suddenly, Dr. Robert Stenhouse Williams, M.B., C.M., D.Sc., Director of the National Institute for Research in Dairying, University of Reading.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Smith, Camb. and St. Thomas's G. L. Talwar, Punjab and St. Thomas's ; J. C. S. Thoma St. Bart.'s ; A. A. M. Wajih, Bengal and Charing Cross ; ar G. Walker, London.

Royal College of Physicians of Edinburgh.

At a quarterly meeting of the College on Feb. 2nd, wi Dr. Robert Thin, the President, in the chair, Dr. Jam Douglas Allan Gray (Liverpool), Dr. John Gibb McC (Edinburgh), and Dr. Douglas Nairn Nicholson (Edinburg were introduced and took their seats as Fellows of t College. Dr. James Waters Thornton Patterson (Droitwic Dr. Jacobus Johannes de Waal (Johannesburg), and I William Lindsay Lamb (Aberdeen) were elected to t Fellowship.

Prof. K. F. Wenckebach, of Vienna, was appointed t George Alexander Gibson lecturer for 1932. Dr. Jam Crooks and Dr. Henry Joseph Rodway Kirkpatrick we awarded the Kirk Duncanson Fellowship for Medic Research, for one year. Lieut.-Colonel John Moriso I.M.S., was awarded the Parkin prize for the best essay the curative effects of carbonic acid gas or other forms carbon in cholera, the different forms of fever, and oth diseases.

London Inter-Collegiate Scholarships Board.

The Board announces that an examination for 14 medi *scholarships and exhibitions, and one* dental scholars of an aggregate total value of £1483, will begin on May 23 They are tenable at University College and Universi College Hospital Medical School, King's College and Kin College Hospital Medical School, the London (Royal F Hospital) School of Medicine for Women, and the Lond Hospital Medical College. Full particulars and entry fo may be obtained from the secretary of the Board, Mr. S. Ranner, the Medical School, King's *College* Hospit Denmark-hill, S.E.5.

National Conference on Leprosy in China.

We are informed that the first national conference leprosy in China will be held in Shanghai on April 14 and 15th, under the auspices of the Chinese Mission Lepers. The first day will be devoted to an appraisal the leprosy position in China, and to discussions on t methods most applicable to the special conditions in th country. The second day will be given to the considerati of problems of diagnosis and treatment. No special invit tions are being sent out, but it is hoped that leprologis from other countries will take part in the discussions.

Brighton County Borough Mental Hospital.

On Feb. 6th, the Mayor of Brighton opened an admissi hospital in connexion with the larger institution at Haywar Heath. There had been hopes of finding a suitable si for building in the grounds of the Mental Hospital, but t adjoining estate of Beechmont, a house of Georgian ty with 27 acres, came into the market, and it was purchas by the Brighton Corporation upon the strong recommend tion of the medical *superintendent,* Dr. G. H. Harpe Smith, and the Board of Control, need for relieving a certa amount of overcrowding in the main hospital having lo been insistent. The purchase price for the estate w £9225 ; £5400 has been spent on its adaptation, and abo £2600 on its furnishing. There is accommodation f 50 female patients at weekly payments ranging from thr to ten guineas.

NOTES, COMMENTS, AND ABSTRACTS

SOME COMMENTS ON THE CONSCIOUS MIND.*

BY ALEX. W. HENDRY, M.D. ABERD., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, ABERDEEN ROYAL INFIRMARY.

IT is perhaps permissible to doubt the wisdom of some prevalent tendencies in psychology. Previously metaphysicians considered consciousness a fundamental condition of all intelligence, and an invariable component of mental action. Present day psychologists would have us believe that most of our mental life is lived in the subconscious. If this be true, if such a state of affairs really exists, then it bodes ill for enlightened endeavour and progressive human advancement.

The subconscious mind has been enthusiastically studied—studied with an intensity which has destroyed the perspective and disturbed the general view of the mental field. It has become but a synonym for the devils and demons of the dark ages. The subconscious is charged with the harbouring of complexes which bring about serious mental discord and ill-health. These complexes may cause paralysis, anæsthesias, obsessions, amnesias, phobias, fits, and fugues. They chase happiness away, and bring untold misery and sadness to whomsoever may possess them. It would appear to be the teaching of the present, that the door to mental harmony lies in the subconscious mind. Have we no key to that door? Can we consciously and deliberately unlock the door? Or has the subconscious locked it against us?

An extensor plantar reflex occurs in, but is not due to a lesion of, the lower motor neurone. It is due to a loss of pyramidal influence. So the vagaries of neurotics are not due to any essential abnormality of the subconscious, but are phenomena associated with lack of higher control. In neurotic cases there is default in conscious mental processes. The unwelcome matter is sidetracked. It never really comes before the highest consciousness, and therefore, its associations are confined to subconscious realms. The "complex" is the result of default, and this default must necessarily be the essential factor in the production of neurotic states. In normal people the default is subject to correction by directive consciousness. The process of repression may be unwitting, but not, it is submitted, outside conscious control. Failure to face unpleasant facts is a weakness of the conscious mind. Normal people must face unacceptable affects, because if such are not consciously faced then repression definitely occurs.

It is noteworthy that Freudians find in all neurotic states evidence of repressed sexuality. These findings are not very convincing. It would be difficult to attribute war neurosis or railway spine to sexual complexes. Human beings have many interests, and while it is true that in psychopathic states of civil life, repressed sexuality is a very important factor, nevertheless, there are other affective states which, if incompletely mentalised, result in neurosis. Sexual complexes have nothing whatsoever to do with a great many cases. Another point is doubtful—Freudians trace complexes back to infantile life. These infantile complexes revealed by psychoanalysis are not in themselves causatively connected with adult neurosis except by regression. In cases of recent origin there has been either a mental deterioration or a new situation which cannot be adequately faced. Where no mental deterioration has occurred some present maladaptation exists—a lack of directive conscious ability for appropriate reaction. The infantile complex in these cases is but a regression, a revitalisation by transference of affect. Many psychopathic states traced to infantile sexual repression are due, not to these infantile complexes, but to a present maladaptation.

Some people there are who spend the major part of waking life in the subconscious. They are awake and yet they sleep. Their actions result from primitive impulses which are not understood, not judged, and not inhibited. Their actions are thus not moulded by the highest critical mental faculties. Perhaps most people are somehow partially cognisant of the true and real reasons for their actions, but few indeed are fully aware of the nature of their impulses, their source or their reason. Few people subject these impulses to the full scrutiny of their critical faculties, so that their final actions may be fully conscious, deliberate, and defined. Such people know themselves. The fuller the consciousness of daily life, the greater the degree of culture, the higher the grade of civilisation. As yet the integration of primitive and highest mental faculties is incomplete. Minds are not fully developed. Man himself must consciously and deliberately accomplish this. He must expand his realism to include his subconscious, only thus is the fullest consciousness possible. Further, mental evolution is likely, but this evolution must be deliberate, directive, and conscious. Man must evolve his own mind.

The division between the conscious and subconscious has been termed a "psychic filter." It is more like a barrier—a movable barrier which recedes as the conscious realm is enlarged. We must penetrate the dark areas, we must switch the mental floodlight from our environment right about into the dark recesses of our minds, and this is possible and is called "introspection." It is not for a moment suggested that children and juveniles are capable of introspection. It is, however, strongly urged that the normal adult would benefit greatly from observation of the inner mental self. The springs of energy should be examined and studied; then only could power be conserved and controlled. Impure springs could be cleansed, wandering streams collected and made to swell the volume of vital energy. Too often is man at the mercy of an all-devouring, harmful mental torrent. This harmful energy can only be harnessed for useful work if pure springs and straying streams are guided into peaceful channels filled with useful energy and quiet harmony. Evolution has brought man to a state of sentiency, and further progress depends on the use of this function. He must, if he would further improve, examine carefully and thoughtfully the mental springs, and he must consciously and deliberately direct their route. More consciousness is required, indeed a superconsciousness is requisite, and this is what we must strive to acquire.

Introspection will bring knowledge and knowledge will bring power, so that in the end man may be able to say truly, "I am the Captain of my Soul, the Master of my Fate." Cultivate then this all-pervading all-knowing consciousness. Know thou thyself. Let no mental ripple escape your consciousness, then you need never fear the subconscious and its terrors.

[*] Substance of lecture delivered before the Aberdeen University Medical Society on Nov. 13th, 1931.

CONTROL OF MALARIA.

AT a recent meeting of the industrial antimalarial advisory committee of the Ross Institute, the formation of an Assam branch was reported, and Dr. G. C. Ramsay gave an account of the work that was being done to prevent malaria on tea estates in Assam and Bengal. A fifth research centre was, he said, being opened during the year. It was also announced that Dr. Ramsay had completed researches into the best oils for antimalarial mixtures and was now in touch with the Burma Shell Group with a view to making a standard efficient mixture available at all the oil

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, Feb. 16th.—5.30 P.M., General Meeting of Fellows: Ballot for election to the Fellowship. 8.30 P.M., Pathology: Papers: R. M. Fry: The Isolation of Organisms in the Presence of *B. proteus*. R. J. V. Pulvertaft: Experiments in Rabbits with the Toxins of the Hæmolytic Streptococci. J. A. Murray: Mesenteric Metastases of the Rous I. Fowl Sarcoma. Spindle-celled Tumour with Prickle-cell Carcinomatous Metastasis. The Structure of the Gizzard. F. R. Selbie: Experiments on the Tomato-juice Sarcoma of Rats.

Thursday.—5 P.M., Dermatology (Cases at 4 P.M.). Short Paper: Dr. H. Windsor Wade (Culion Leprosy Settlement, Philippine Islands): Tuberculous Leprosy. Cases: Dr. H. W. Barber: 1. Telangiectasia macularis eruptiva perstans (Parkes Weber). 2. Acanthosis nigricans: forme fruste. Dr. G. B. Dowling with Dr. L. Forman: 3. Fox Fordyce Disease. Dr. J. M. H. MacLeod: 4. Acne Scrofulosorum. 5. Case for diagnosis. Dr. W. N. Goldsmith: 6. Bowen's Disease with Prickle-celled Carcinoma and Associated with Psoriasis. Other cases will be shown. 8.30 P.M. Neurology. Short Papers: Dr. C. P. Blacker: Human Pedigrees. Dr. J. le F. Burrow: The Phenomena of Regeneration in Peripheral Nerves After Suture. Dr. Ranyard West: Curare in Man.

Friday.—5.30 P.M., Physical Medicine. Paper: Dr. T. G. Kahlmeter (Stockholm): Modern Physiotherapeutic Measures. 8.15 P.M., Obstetrics and Gynæcology. Discussion: Gonorrhœa and Other Cervical Discharges. Opener: Colonel L. W. Harrison (St. Thomas's Hospital). 8.30 P.M., Radiology. Discussion: X Ray Treatment of Non-malignant Conditions. Short Papers: Dr. Russell Reynolds: 1. The X Ray Treatment of Mastitis and Certain Leukæmias. Dr. S. Gilbert Scott: 2. Recent Advances in the Treatment of Rheumatism and Asthma. Informal discussion on general subjects will follow.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 26, Portland-place, W.

Thursday, Feb. 18th.—8.15 P.M., Dr. C. C. Chesterman: Some Results of Tryparsamide and Combined Treatment of Gambian Sleeping Sickness. (Demonstration at 7.45 P.M.)

CHELSEA CLINICAL SOCIETY, Hotel Rembrandt, Thurloe-place, S.W.

Tuesday, Feb. 16th.—8.30 P.M. (preceded by dinner at 7.30). Discussion on Medical Evidence in Criminal Cases. (To be opened by the Master of the Rolls and Sir William Willcox.)

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Upper Montague-street, W.C.

Friday, Feb. 19th.—5 P.M., Discussion on Rheumatism in the School Child. (To be opened by Dr. Gerald Slot, Dr. Francis Bach, and Dr. Vincent Coates.)

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

Friday, Feb. 19th.—5 P.M. (at 11, Chandos-street, W.), Dr. William Moodie: The Significance of Abnormal Behaviour in Children.

ROYAL INSTITUTION, 21, Albemarle-street, W.

Thursday, Feb. 18th.—5.15 P.M., J. B. S. Haldane: Heredity in Man.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

Thursday, Feb. 18th.—5 P.M., Prof. Cyril Okell: The Rôle of the Hæmolytic Streptococci in Infective Disease. (First Milroy lecture.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

Monday, Feb. 15th.—4 P.M., Mr. Wilfred Trotter: The Hunterian Oration.

Wednesday.—5 P.M., Prof. Le Gros Clark: Structure and Connexions of the Optic Thalamus. (Arris and Gale lecture.)

Friday.—5 P.M., *Prof. Le Gros Clark (lecture continued).*

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

Monday, Feb. 15th, to Saturday, Feb. 20th.—Medical Society of London, 11, Chandos-street, Cavendish-square. Wed., 4 P.M., Mr. P. Lockhart Mummery: Lantern Demonstration, Diagnosis and Treatment of Diverticulitis.—East London Hospital for Children, Shadwell. Tues., Demonstration by Dr. Leonard Findlay, at 3 P.M.—Metropolitan Hospital, Kingsland-road, N. Thurs., Demonstration by Mr. C. Naunton Morgan, at 2 P.M.—Prince of Wales's Hospital, Tottenham, N. All-day course in Medicine, Surgery, and the Specialties, 10.30 to 5.30 P.M.—Royal Free Hospital, Gray's Inn-road, W.C. Fri., Demonstration by Prof. Dame Louise McIlroy, at 5 P.M. Further particulars from the Fellowship of Medicine.

NATIONAL HOSPITAL, Queen-square, W.C.

Monday, Feb. 15th.—2 P.M., Dr. Riddoch: Out-patien
Clinic. 3.30 P.M., Dr. Symonds: Disseminate
Sclerosis and Allied Conditions.

Tuesday.—2 P.M., Dr. Walshe: Out-patient Clini
3.30 P.M., Dr. Martin: Diseases of the Vertebr
Column with Nervous Symptoms.

Wednesday.—2 P.M., Dr. Martin: Out-patient Clinic.

Thursday.—2 P.M., Dr. Kinnier Wilson: Out-patie
Clinic. 3.30 P.M., Dr. Critchley: Cerebral Sclero
of Childhood.

Friday.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.
Dr. Walshe: Cerebral Tumours.

GUY'S HOSPITAL, London Bridge, S.E.

Monday, Feb. 15th.—5 P.M., Dr. A. E. Barclay: The U
of X Rays in Physiological Investigation.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

Tuesday, Feb. 16th.—3.15 P.M., Mr. F. Roques: Pregnan
in Association with Tumours.

HAMPSTEAD GENERAL AND NORTH-WEST LONDO
HOSPITAL.

Wednesday, Feb. 17th.—4 P.M., Dr. W. E. Gye: Canc

CITY OF LONDON MATERNITY HOSPITAL, City-roa
E.C.

Thursday, Feb. 18th.—5.30 P.M., Dr. H. C. Luce
Pathology of Pregnancy.

ST. PETER'S HOSPITAL, Henrietta-street, W.C.

Wednesday, Feb. 17th.—3 P.M., Mr. R. Ogier War
The Investigation of Hæmaturia.

ST. MARK'S HOSPITAL, City-road, E.C.

Thursday, Feb. 18th.—4.30 P.M., Mr. E. T. C. Milligo
Pruritus Ani.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOO
University-street, W.C.

Tuesday, Feb. 16th.—5.15 P.M., Prof. A. E. Boyco
Hypertrophy and Atrophy.

CHARING CROSS HOSPITAL MEDICAL SCHOOL.

Sunday, Feb. 14th.—10.45 A.M., Dr. R. A. Hickli
The Differential Diagnosis and Treatment of Brea
lessness. 11.45 A.M., Dr. S. C. Shanks: X
Diagnosis in Urinary Conditions.

KING'S COLLEGE HOSPITAL MEDICAL SCHO
Denmark-hill, S.E.

Thursday, Feb. 18th.—9 P.M., Dr. J. L. Livingst
Bronchiectasis—Its Prevention and Treatment.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospi
Leicester-square, W.C.

Tuesday, Feb. 16th.—5 P.M., Dr. M. Sydney Thoms
Lupus Erythematosus.

Thursday.—5 P.M., Dr. I. Muende: Pathology Dem
stration.

SOUTH-WEST LONDON POST-GRADUATE ASSOC
TION, St. James' *Hospital, Ouseley-road,* Balham.

Wednesday, Feb. 17th.—2.30 P.M., Dr. A. Salway:
to Oxo, Ltd.

CENTRAL LONDON THROAT, NOSE, AND EAR H
PITAL, Gray's Inn-road, W.C.

Friday, Feb. 19th.—4 P.M., Mr. H. Kisch: Treatmen
Cancer of Throat, Nose, and Ear by Radium.

CHADWICK LECTURE.

Thursday, Feb. 18th.—5.15 P.M. (at the Medical Soc
of London, 11, Chandos-street, W.). Dr. J.
Rolleston: Sir Benjamin Ward Richardson, his
and Work (illustrating epidiascope).

BRITISH INSTITUTE OF RADIOLOGY, 32, Welb
street, W.

Thursday, Feb. 18th.—8 P.M., *Prof.* M. S. Pembrey
others: Influence of Muscular Work on the Pas
of Food through the Stomach of Man. Dr. A. G
Taylor: Action of Radium D, E, and F with Collo
Bismuth upon Growing Tumours. Mr. W. J.
and Mr. L. H. Clark, Ph.D.: Quantity and Significa
of the Scattered Radiation produced in Water Subje
to Beams of X Rays and Gamma Rays.

Friday.—2 P.M., Mr. Philip Franklin and Dr. A. Or
Demonstration of Lipiodol Bronchography by
Nasal Route.—5 P.M., Cases for discussion.—5.30
Dr. F. Hernaman-Johnson: Experiments on
Projection of the Sphenoidal Sinuses through
Orbit. Dr. S. L. Mucklow: Relief of Pain in Rheu
toid Arthritis and Myositis Ossificans by Ray Thera

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Rus
square, W.C.

Wednesday, Feb. 17th.—4 P.M., Dr. A. R. Nelig
Organisation of Treatment for Industrial Rheumat

NATIONAL COUNCIL FOR MENTAL HYGIENE.

Friday, Feb. 19th.—4.15 P.M. (at the Whitworth-st
West Hospital), Mr. Morley: Birth Injuries
Their Treatment.

FACULTY HALL, St. Vincent-street, Glasgow.

Tuesday, Feb. 16th.—4 P.M., Prof. A. Young: Surg
Treatment of Minor Infections.

VICTORIA INFIRMARY, Glasgow.

Wednesday, *Feb.* 17th.—4.15 P.M., Mr. R. Tenne
Surgical Cases.

ADDRESSES AND ORIGINAL ARTICLES

THE COMMEMORATION OF GREAT MEN.*

BY WILFRED TROTTER, M.S. LOND.,
F.R.C.S. ENG., F.R.S.,
SERJEANT SURGEON TO THE KING; SURGEON TO UNIVERSITY COLLEGE HOSPITAL, LONDON.

I.

EVENTS that recur with a regular period are apt to be taken as a matter of course, to have their significance regarded as obvious, and to seem in no need of justification. To resist this tendency to confuse the familiar with the obvious is one of the most necessary efforts the mind is called upon to make. The institution whose recurrent activity we take part in to-day was set up 119 years ago, and marks a birthday since which 204 years have passed. For more than a century orations have been delivered on the life and work of Hunter, and they have explored their theme from every aspect and adorned it with every art. The high qualities of these orations make it impossible for a new contributor without special aptitude to hope for any freshness in the presentation of a topic already so well discussed by better men. On the other hand, the imposing length of the series may perhaps have a little obscured our apprehension of the more elementary meanings that underlie these regularly returning occasions. Under the pressure of these converging indications it will be my relatively humble task to seek answers to such questions as the first giver of this oration might be supposed in his preliminary musings to have put to himself. What are the reasons, we shall want to know, why John Hunter should be regarded as a fit subject for enduring celebration, and what do we wish and what do we attain in the many activities by which in general we pursue, or suppose ourselves to pursue, the commemoration of great men?

II.

To question established beliefs is nowadays perhaps a rather old-fashioned activity. We may be sure, nevertheless, that it is one of which Hunter would thoroughly have approved even if his own greatness was to be in question. In that case, however, if we are to judge by his known methods in controversy, the discussion would go all the smoother if we hinted beforehand what the verdict was to be. For of the verdict there can be no doubt, and it will find that the makers of this recurring celebration not only chose an exceptionally sound foundation but built perhaps a great deal better than they knew.

Hunter was a successful surgeon with a large practice and a correspondingly ample income. It must not be suggested here that that is anything but highly respectable attainment. It is not, however, attainment that, under any magnification or however many ciphers may be subtracted from the mortality of his patients and added to his income, reveals in its creator the heroic features we are seeking.

Hunter made the museum which for over a century has been the very focus and palladium of this College. In this work we find the giant energy and resolution of true greatness directed by a correspondingly clear and ample idea. It was no mere miscellaneous assemblage of odds and ends as the collections of his contemporaries tended perhaps a little to be, but a grouping of orderly series nobly illustrating the living world and the processes of disease. It is scarcely possible for the richness and order of this historic monument to be spoken of too highly, but it may be doubted whether in themselves they could have given to their creator his unique and enduring prestige.

Hunter was a consistent and expert user of the experimental method in the study of living processes, and it is on this fact that his fame essentially and ultimately rests. It was by impressing this method on his pupils and successors that his services to science and to surgery have had their most extended and their richest effects. These experimental studies covered a very wide field and dealt with fundamental problems such as the process of repair, the survival of isolated tissues, transplantation, grafting, inflammation, the processes of growth, and the influence on them of the sexual glands. Such researches were pursued with unfailing zeal and ability, and yielded results of importance in many directions. It is impossible, however, not to be struck by a certain disproportion between the amount of energy and genius that was expended, and the harvest of substantial knowledge that was gathered. Many of the researches were indecisive, not a few of the conclusions were incorrect, and no single advance was won which could be said to mark an epoch in the history of knowledge. Every student of Hunter is convinced that he belonged to the very small class of those who possess powers of the first order; few can be equally convinced that he made a direct contribution to the science of his day fully commensurate with his splendid gifts. It is therefore particularly happy that his commemoration should have been formally assured and entrusted to an enduring institution. Other experimental workers in the science of life, more fortunate but perhaps not more richly endowed, have by their labours so contributed to the very structure and substance of knowledge as to be sure of remembrance without any specific memorial. Of Harvey, of Pasteur, of Lister every student of physiology or pathology is in some sense the beneficiary and direct legatee. The influence of Hunter was more limited to the indirect and germinal; he did not make an epoch, he founded a school.

III.

That Hunter's prodigious powers and devotion yielded such comparatively moderate accessions to knowledge is perhaps not without a certain shade of mystery and pathos. It is an idle occupation for the common man to busy himself with explaining the successes and failures of greatness, but it is no undue presumption to turn our attention to the circumstances of Hunter's life in the search for light upon his career. He was so resolutely modern in his attitude towards the problems of life, and he accepted so whole-heartedly the working hypothesis of their solubility, that we are apt to forget the state of knowledge of his time. During the 65 years of Hunter's life from 1728 to 1793 the biologist could look for practically no help from the sciences of the inorganic, and was without almost every article of equipment we now regard as essential to experimental work. We are accustomed to associate with the earliest foundations of modern chemistry and physics the great names of Cavendish, Priestley, Galvani, Volta, and Lavoisier. Every one of them was junior depôts in India. A standard mixture for South Africa and Rhodesia had been established.

---

* The Hunterian Oration delivered before the Royal College of Surgeons of England on Feb. 15th, 1932.

Mr. P. J. Parker, of the Roan Antelope Copper Mines, Rhodesia, testified to the remarkable results of the work of the Institute there; a large community of some 1800 Europeans and 12,000 natives were now practically free from malaria, mosquito nets were no longer necessary, hardly anybody took quinine, and the social status of the mines had undergone a complete change as the best type of white miner came freely. Sir Malcolm Watson said that he was leaving for a second tour of inspection, for he would not be satisfied by anything less than complete success. Despite the reduction of malaria to less than 5 per 1000 among white people, about 40 per cent. of the 1500 native children were infected, and these he hoped to cure. Sir Malcolm thought that, although Paris green might have a place in malaria control, it was not a substitute for oiling, since it allowed the female mosquito to alight anywhere and lay her eggs in perfect safety. It was quite incorrect to say that it was impossible to control malaria by antilarval measures alone; the disease had been practically stamped out, for example, in the Malay town of Klang without the use of a single grain of quinine. At the same time it was the duty of workers to cure the sick and particularly the children. He was taking two new drugs to Africa for experiment, for some of the results with plasmoquine had been disappointing.

Similar reports of success in stamping out malaria were brought from East Africa, South Africa, and Italy, illustrating the value of the work of the Institute to the commercial and industrial world.

STERILISATION OF THE TYPHOID CARRIER BY OPERATION.

FOR several years the problem of the typhoid carrier has been systematically studied at Gade's Pathological Institute in Bergen, the staff of which is making a survey of typhoid carriers over a large section of the west coast of Norway. Earlier communications have now been supplemented by a paper[1] in which Dr. T. M. Vogelsang and Dr. M. Haaland record 15 new cases, thus bringing up the total number of carriers studied by the institute to 14 men and 58 women. The case histories make sad reading; the fate of the typhoid carrier to-day is in one way even worse than that of the leper in the past. For the leper had often his fellow-sufferers as companions, whereas it is not the custom to form colonies of typhoid carriers—though this may be done eventually. Meanwhile what happens? One of the carriers included in the present survey was a widow for whom a cottage on a lonely island was provided by the local authorities. The inevitable happened, and her return to the haunts of her fellow-beings led to the usual crop of new cases, one at least of which was fatal. It is with such a background as this that the most radical operative interference must be judged; and it is encouraging to find in how great a proportion of cases operations on the gall-bladder sterilise the carrier. Among the 27 operations on the gall-bladder performed on carriers in the series under review, there were two at which the condition of the gall-bladder was found to warrant cholecystotomy alone. In one of these cases the carrier state ceased. Among the 25 carriers on whom cholecystectomy was performed, there were as many as 19 definitely cured. There was one death from operation, and another death 18 months later from tuberculosis, the excretion of *Bacillus paratyphosus* B having persisted after the operation. They had secured a footing in the liver in which necrotic tuberculous foci were found. Of the remaining four failures, two were associated with gall-stones, and it is probable that in both these cases the typhoid infection had ascended the biliary passages within the liver. In the remaining two cases the gall-bladder was found to be normal and the bile sterile. Presumably the typhoid bacilli came from some other organ.

Vacancies

For further information refer to the advertisement columns.

Aberdeen City (Fever) Hospital.—Jun. Rs. M.O. £100.

Auckland General Hospital, New Zealand.—Med. Supt.

Birmingham General Hospital.—Res. Surg. Reg. £100-£120 £140.

Bootle General Hospital, Nr. Liverpool.—Cas. O. and H.S.'s Each at rate of £150.

Bradford Municipal General Hospital, St. Luke's.—H.P.'s and H.S.'s. Each at rate of £200.

Brighton, Sussex Maternity and Women's Hospital.—Res. H.S £130.

Charing Cross Hospital, Strand, W.C.—Surg. Reg. £150. Als Obstet. Reg. £100.

Carlisle, Cumberland Infirmary.—H.P., 2nd H.S., and H.S. t Spec. Depts. Each at rate of £155.

Derby, Derbyshire Royal Infirmary.—Cas. O. £150.

Doncaster Royal Infirmary.—Sen. Cas. H.S. At rate of £175.

Dudley, Guest Hospital.—H.S. £200. Also Asst. H.S. £17

Elizabeth Garrett Anderson Hospital, Euston-road.—Obste Asst. £50.

General Lying-in Hospital, York-road, Lambeth, S.E.—Jun. Re M.O. and Anæsthetist. At rate of £100.

Great Yarmouth General Hospital.—Sen. and Jun. H.S.'s. A rate of £150 and £140 respectively.

Hospital for Consumption and Diseases of the Chest, Bromplo S.W.—Physician. Also Asst. Physician.

Huddersfield Royal Infirmary.—H.S. At rate of £150.

Islington Dispensary, 303, Upper-street, N.—Asst. Res. M. £250.

Leeds University.—Lecturer in Experimental Pathology a Asst. Director of Cancer Research.

Leicester Royal Infirmary.—H.S. and H.P.'s. Each at rate £125.

Liverpool City.—Asst. Tuberculosis O. £500.

Liverpool, Royal Babies Hospital, Woolton.—Res. M.O. At ra of £90.

London Lock Hospital, 91, Dean-street, W.—Surg. Reg. £1

London Lock Hospital, Harrow-road, W.—Surg. Reg. £100.

Maidstone, West Kent General Hospital.—H.S. £220.

Manchester, Ancoats Hospital.—Two H.S.'s. Each at rate of £1 Also Med. Reg. £50.

Manchester Babies Hospital, Burnage-lane, Levenshulme.—Ju Res. M.O. At rate of £50.

Manchester and Salford, Hospital for Skin Diseases.—H.S. rate of £100.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Margaret-street Hospital for Consumption, W.—Hon. As Phys.

Metropolitan Hospital, Kingsland-road, E.—Surgeon.

Northwood, Middx., Mount Vernon Hospital.—H.S. £150.

Nottingham General Dispensary, Broad-street.—Res. Surge £250.

Paddington Green Children's Hospital, W.—Hon. Dental S. a Hon. Surgeon to Out-patients.

Plymouth, South Devon and East Cornwall Hospital.—H.S. rate of £100.

[illegible] Hon. Surgeon.

[illegible] *Hospital.*—H.P. At rate of £1 £180.

[illegible] *Inn-road, W.C.*—Asst. Surgeon Ear, Nose and Throat Dept.

Royal National Orthopædic Hospital, 234, Great Portland-str W.—Hon. Dental Surgeon.

Royal Waterloo Hospital for Children and Women, Waterl road, S.E.—Hon. [illegible] Also Hon. Med. R

Salford Royal Hospita [illegible] *N.W*

Samaritan Free Hosp [illegible] H.S. At rate of £100.

Sheffield, Jessop Hospital for Women.—H.S. At rate of £1

[illegible] *spital, Harlesden-road, N.W.*—Hon. 2

[illegible] *VII. Hospital.*—Res. M.O. £200.

The Chief Inspector of Factories announces vacant appointme for Certifying Factory Surgeons at Kingston (Surrey), Presteign (Radnor).

---

[1] Norsk Mag. f. Laegevidenskaben, November, 1931.

increasing divergence between the subject commemorated and the object commemorating has perhaps its consolations when we view the objects of memorial art in our public places. At any rate, we may tell ourselves as we shrink before the marble frock coats and the bronze beards and whiskers, their supposed subjects could scarcely have been like that. However forlorn in the eyes of mere reason the task of keeping in being the veritable personality of the dead, mankind has addressed itself to this object throughout the ages. And its efforts have always illustrated the twin themes of pity and fear. The hunter warrior must have his weapons and his dogs with him in the grave, the head of the house his servants and his wives, and both their finery and their food. So they would be happy and at ease, and the bereaved could feel a little comforted; and if they were happy and at ease perhaps they would not come back.

When the dead man is a great man, another theme is added revealing motives with the same rich human mixture of the noble and the base. The qualities of the hero are worshipped, are desired, and are pursued with devotion and without scruple. Primitive man seems very early to have thought the most obvious way to assimilate the virtues of the hero was to assimilate his body, actually to eat his flesh in the expectation that the spirit which had animated it would also be conveyed and absorbed—a robuster conception of organotherapy than we have yet come back to. Hence arises the commemorative feast which has penetrated Western civilisation with what huge significances we know. A second idea which belonged more definitely to the realm of magic was to make an image of the hero, and so preserve his personality without limit; thus the qualities most desired could be judiciously magnified, and, above all, the whole conception was under control.

But the primitive mind with its dangerous gift of logic could not leave the subject without further rational expansion. If heroic virtues are transferable at death, must one wait upon the operation of mere natural processes? We need not doubt that the plain conclusion has been on due occasion reached. When the slayer was assured of acquiring the virtues of the slain, the crazy logic of memorial piety had reached its climax. This dark theme wanders elusively in the customs and folk-lore of early man, and has its classical seat where in the shadowy southern woods we discern the enigmatic figure of the Priest of Nemi with the Golden Bough.

It would be easy to fall into absurdity by making crude and over-simplified applications of these primitive modes of thought to our modern affairs. Nevertheless we must not forget the ingrained conservatism of Nature; physiology has shown to how large an extent the fundamental chemistry of the body and the elementary working of the nervous system tend to be uniform throughout the animal world.[1] There is good reason to suppose that the same kind of elementary uniformity obtains, and has always obtained, in the reactions of men's minds. If the ideas we have indicated occurred in primitive minds we may be sure that manifest or latent evidences of them will be found in our own. At any rate, we cannot deny that the commemorative feast has its part in modern memorial celebrations; or that man still likes to make magic images of his heroes—though there may be little enough magic about some of them—and to magnify the features he thinks they ought to have, and suppress the others.

It would partake too much of the nature of the overstrained ingenuity I have already deprecated to enlarge upon the traces of what we may call the Golden Bough theme that are to be found in the treatment by society of its men of exceptional character and capacity. Such traces are to be met with, but they are perhaps too elusive to be put into words without an effect of crudity and exaggeration.

V.

The *conscious* and *ostensible* motives under whose influence we approach the commemoration of great men are first, to contemplate in humble piety and emulation a largeness of mind and character that far exceed our own; and, secondly, to seek inspiration from struggles heroically engaged and perhaps triumphantly won. There is no commoner mistake in practical psychology than to suppose that because a motive is admirable it must therefore be strong. If we are to be honest with ourselves we shall have to admit that aspirations such as these do not accompany us very far along the humdrum and ignoble ways of daily life. Many of us, I fear, must have felt guiltily conscious of how little the exhilaration produced by such exercises has been able to compete with the trivial anxieties and ambitions of our own pedestrian lives. Side by side with this weakness in our conscious motives there is, as I have hinted, reason to suspect the presence of other and submerged impulses, the vestiges of a cruder, harsher, type of feeling, which for all their dimness may have a certain ugly strength. When we remember, in addition, the difficulty of establishing and keeping alive the true and unadulterated personality of the dead, we must, I think, confess that the art of ceremonial commemoration has to overcome obstacles of a very formidable kind if it is to avoid becoming increasingly formalised and superficial.

It is possible that a future and more realistic age may reach the conclusion that the time to celebrate its heroes is while they are alive, and not to wait with our remarkable patience until they are safely dead. Such an age will perhaps reason in its clear way that its duty towards its great men is to get as much out of them as it can, and that no piety after their death can equal in effectiveness for the purpose a receptive and sympathetic understanding during their lives.

VI.

It is unfortunately very much easier to recognise a man's greatness after he is dead and when we are freed from the distraction of the actual presence which unhappily tends so often to be odd, angular, and even quarrelsome. It is also an old story that the reception of new ideas tends always to be grudging or hostile. The text is a favourite one, and is apt to become the theme of exhortations which, in addition to having the dreariness of their kind, are pointless because they constitute a frontal attack on an ingrained quality of the mind.

Apart from the happy few whose work has already great prestige or lies in fields that are being actively expanded at the moment, discoverers of new truth always find their ideas resisted. The consideration of this process is often obscured by two assumptions: first, it is supposed that the most harmful resistance comes from obvious and noisy prejudice, and that the resistance of inertia and quasi-rational negation is unimportant; and, secondly, it is supposed that workers in science are of course free from any to Hunter. Let us for a moment regard the situation of Hunter in his prime in 1765. He would have had to wait ten years for Priestley's discovery of oxygen in 1775; he would have had to wait over 60 years for Wohler's synthesis of urea and the foundation of biochemistry in 1828, and nearly 80 years for Joule's mechanical equivalent of heat. Over 60 years ahead was Joseph Jackson Lister's completion of the compound microscope, which made possible the science of histology, and exactly a century away, the proof of the nature of wound infections by Lister's greater son.

---

[1] Hopkins, Sir Gowland: Anniversary Address, Proc. Roy. Soc., January, 1932, p. 420.

In this atmosphere of embryonic science and primitive equipment Hunter worked with high faith and energy at problems which have resisted, or yielded only grudgingly to, all the resources of the modern world. Not only was there little help for him in the general body of science, but biology itself lay in a certain sense between two tides of inspiration. The gross structure of the animal body had been fully exploited by the great anatomists; the stimulus this had given to knowledge had come to the flood and was ebbing fast. Exact histology lay half a century in the future, and for the want of it most of Hunter's experiments could not be given full exploitation or carried to exact conclusions. It needs all our imaginative sympathy to picture the twilit country in which his labours were carried on—the air is dim and thick, the range of vision short, the appearance of things ambiguous,

> —"the tired waves vainly breaking
> Seem here no painful inch to gain."

We can scarcely resist the sense that there was a prophetic element in the feverish energy with which he set himself to his tasks. For events were to give to such work a new value and a new necessity The long climax of the eighteenth century was passing by. Ahead lay a changed order where social structure would have an unheard-of complication and biological problems an unheard-of urgency. The world seemed to pause, gathering itself for the plunge. The movement would be slow at first but presently would take on a vertiginous acceleration.

In 1774, when Hunter was 46 and in the full tide of work, a young Scotchman named James Watt left Glasgow for Birmingham to become the partner of Matthew Boulton, and with his help to add to the gathering forces of the industrial revolution the immense momentum of the steam-engine. There followed a commercial expansion and a crude industrial hypertrophy which made this country the envy of the world, but which we can now contemplate with only a qualified pride. The growth of trade and population was so imperious and so exuberant that the ordinary hygienic difficulties of social life increased out of all bounds. Industrial areas of population grew unchecked by regard for space, for decency, or for health, while the discrepancy between the rate of development of mechanical and biological knowledge became more and more dangerously wide. The great, but as we can now see rather Grecian, gift made by the North to the South, when James Watt brought the steam-engine to England, was to be repaid in a nobler and less equivocal form when 86 years later a young Englishman named Joseph Lister went to Glasgow. The industrial revolution and the steam-engine had done their work. To the great new industrial populations hospitals had become more and more indispensable, and with every enlargement of their activities they had become more and more dangerous to their surgical patients. The process was a progressive one for a reason that is now obvious, the frequent occurrence of infection from patient to patient being ideally suited to raising the virulence of micro-organisms to the highest pitch and maintaining it there. Surgery in hospitals was in fact already threatening to become extinct.

It was in this darkest hour that the method of Hunter brought off its greatest stroke. Of that method Lister was a devout and explicit disciple. In five years from his going to Glasgow he had solved the problem of wound infection and modern surgery was born.

The lapse of time, with its slow revelation of perspective and proportion in the succession o events, seems more and more clearly to teach th lesson of Hunter's career. It was not as a surgeon as the maker of his great museum, or even as discoverer in science, that his greatness was reveale or his influence perpetuated. It was by his exampl in the use of the scientific method—faithfully, i purity of heart, and with utter devotion to truth.

IV.

We cannot examine even in this hasty way the specia instance of a given memorable man without feelin a logical pressure towards the consideration of th more general case, of the meaning and motives tha underlie one of the most widespread of human impulses We assume that the commemoration of heroes i possible and to be desired, and it would perhaps b well in prudence to leave it at that, for the momen we pierce the smooth surface of the assumption w find ourselves in a world of ambiguities and uncomfortable hints. Nevertheless, it is perhaps a health exercise in an environment such as this—so soli so stable, so justly confident—to recall to ourselve sharply that these also are appearances.

Let us begin by planting squarely before us th plain fact of death. I make that specious reques not in the expectation that it will be granted, for is in the very nature of that fact's relation to li that we cannot get a square, collected, and, as it wer binocular look at it. A living mind can form n intimate conception of its own death, and is apparentl for ever incapable of comprising two categories whic are not opposites, as is often crudely supposed, bu superlatively different. And yet in the world gross reality the expectation of death for the individu is the one prospect for which the attestation experience amounts most nearly to philosoph certainty. This radical antinomy in the life of eve conscious being, in spite of having been the chi preoccupation of the speculative mind since it cam into existence, remains and must remain unresolve Among the by-products of these secular activiti is the strange jumble of sense and fantasy that mak up our attitude towards the memory of the dead.

In even its most sober and enlightened momen mankind has regarded the dead with fear and pit In other moments the feeling has risen to awe an reverence, or has sunk to a strange blend of horr and contempt. The mixture of feeling has withdraw attention from the central fact, that from the momen of a man's death the memory of him begins to fad for he has entered on a new state about which th only certainty is that it has nothing to do with lif Nothing can arrest this decline, no memorial can d more than delay it, and as it delays distort. In a our commemorations. whether by word or by plasti art, we make our own pictures and drift increasingl away from the actual man. These are the re ghosts, and nothing brings more certain convictio of a man's death than his memorial. This steadil illimitable ocean of biology before him, and he addressed himself unhesitatingly to explore it all. It was in the general level of knowledge and in instrumental equipment that he was less fortunate. When a new Hunter appears he will not be held back by an undeveloped science, and he will find this College able to give him all the facilities with which it has been munificently endowed. Let us hope that he will also find an intellectual environment where even his most revolutionary ideas will be planted in a nourishing soil and bathed in a genial air.

ARTERIAL ATONY AND ARTERIO-SCLEROSIS.

BY J. PLESCH, M.D.,

PROFESSOR OF INTERNAL MEDICINE IN THE UNIVERSITY OF BERLIN.

THIS paper sets out the thesis that arterio-sclerosis is only one phenomenon in a constitutional systemic disease affecting more particularly unstriped muscle. The disease is by no means restricted to local areas; on the contrary, it attacks the whole vascular system simultaneously. The local changes, which we call atheroma, athero-sclerosis, ossification of the arteries, and a number of other names, serve the purpose of strengthening the walls of excessively dilated blood-vessels at points of greatest strain. Arterio-sclerosis is a disease that sets in at every age, that can be arrested, and that can be cured in the early stages and beneficially influenced in the later stages; it is not an ailment of old age which must of necessity be progressive and incurable.

Even by purely local observation, it would be possible to distinguish between two forms of arterio-sclerosis—namely, the arterio-sclerosis of old age, due, in the strict sense of the words, to wear and tear, with its local atheromatous calcified areas as secondary mechanical hysteresis, and arterio-sclerosis as a disease in itself, a constitutional systematic allergic primary affection of the smooth muscles, the sympathetic nerves, and the connective substance. These two types appear clinically quite independently of each other. Even though the pathological anatomical alterations show no characteristic indications of the one or other type of the disease, and even if the histological pictures are vague or very much alike, we are, nevertheless, compelled at the bedside to make a clear distinction between these two forms of the disease for a very great number of reasons. Just as we are quite content to look upon presbyopia as a natural wear-and-tear disease of the eye but are wont to regard all hypermetropia originating from other causes as a disease, sui generis, so also must the "presbyopia" of the arteries be distinguished from arterio-sclerosis as a disease.

The essential characteristic of arterio-sclerosis cannot be the deposition of lime, for at every age, even in infancy, lime is found in the arterial walls in a surprisingly large number of cases. The primary cause of arterio-sclerosis is the weakening both of the muscular and of the elastic elements of the walls of the blood-vessels. If the weakened blood-vessels are not able to offer sufficient resistance to the blood pressure they become stretched and dilated. At points particularly exposed to dynamic pressure alterations occur which in the end serve no other purpose than to raise the resistance of the walls. This process of alteration, which is completed by the deposition of lime plates, offers protection against rupture. Calcification and ossification are, therefore, not a disease but a healing process. The first local changes caused by excessive wear and tear in parts of the vascular walls are anatomically characterised by proliferation of the tunica intima at quite an early stage.

L. Ernst, in his excellent investigation, was able to study the differentiated structure of the muscular and elastic elements of the vascular walls. These investigations substantiate a clinical assumption which we made some time ago—namely, that the various layers and the specific elements of the arterial walls are involved to a varying degree in the disease process. Corresponding with the longitudinal and transverse tonicity of vascular walls, there must be longitudinal and transverse muscles that act independently of each other. The tone of the specific elastic elements must also be taken into account, because longitudinal extension narrows a blood-vessel, and an excised blood-vessel becomes shorter. The two muscular symptoms are functionally, and therefore also clinically, quite dissimilar in their behaviour. The annular muscles counteract more particularly the internal pressure of the blood-vessel, and the longitudinal muscles its longitudinal extension, while the elastic fibres of the artery regulate both strain and pressure.

Pathological Anatomy.

In addition to these arguments, mention must also be made of the following pathological anatomical factors:

(1) The atheromatous changes and calcifications occur at points most exposed to the impact of the dynamic force and where the whirl of the blood stream is strongest. Consequently the points of predilection must lie at the bends of the channel; in the aorta the points involved are the bulb and the posterior wall, and, more particularly, those points where the arteries branch off. Further, calcification chiefly takes place in those arteries most subject to wear in consequence of increased local pressure; for instance, in manual labourers in the arteries of the right arm, in waiters in the arteries of the legs.

(2) It is exceedingly uncommon for an artery to rupture at the point of calcification. So, even in sanguineous cerebral apoplexy, we hardly ever see a rent in the calcified area, practically always in an apparently intact part.

(3) Everywhere in the human body where encapsulation takes place as the result of a morbid process (tuberculosis, echinococcosis, myomata, cysts of all kinds) we find calcareous deposits besides an accumulation of cholesterin. There is nothing to prove that arteries in this respect fall into a different category.

(4) That the more heavily taxed parts of the blood-vessel require an arterio-sclerotic protection can be proved by the nodular form of arterio-sclerosis. We find the latter in arteries which are curved and show numerous branches—e.g., the coronary arteries, the carotids, the cerebral vessels, the subclavian artery, and the arteries of the intestines. Arteries that can easily be moved in their substratum, such as the arteries running across the joints, are not involved (G. Oberndoerfer). In unilateral goitre, the curved, laterally displaced, carotid artery becomes calcified, while the normal undisplaced carotid remains unchanged. On the other hand, diffuse arterio-sclerosis appears in arteries which in parts have a straight course with but few branches. Here there is a uniform thickening along the whole length of the vascular walls due to the action of increased local

resistiveness beyond a rational conservatism. Each of these assumptions is an almost complete delusion.

The vociferous opposition met with by the ideas of Charles Darwin and of Lister probably did nothing to hinder the spread of these, and probably brought them within reach of a larger number of people capable of accepting them than would have been the case if the opposition had been well behaved. Again it was not noisy prejudice that caused the work of Mendel to lie dead for 30 years, but the sheer inability of contemporary opinion to distinguish between a new idea and nonsense. That this same inability may be shown even by the most eminent workers in science scarcely needs demonstration for anyone at all aware of the history of knowledge, but it may be illustrated by an anecdote which we owe to the third Lord Rayleigh and which is to be found in the delightful *Life*[2] of that very great and wise man. J. J. Waterston was an engineer who interested himself in mathematical physics, and in 1845 wrote a paper on the molecular theory of gases which was 10 or 15 years in advance of his time and anticipated much of the work of physicists no less eminent than Joule, Clausius, and even Clerk Maxwell. The only contemporary judgment on this paper that survives is that of the referee of the Royal Society to whom it was submitted. He said: "The paper is nothing but nonsense." What Waterston might have accomplished if he had had the recognition and encouragement upon which this genius seems to have been unusually dependent, is beyond conjecture. He did not get them. His work lay in utter oblivion for 45 years until it was exhumed by the pious efforts of Rayleigh. He himself lived on disappointed and obscure for many years, and then was overtaken by a yet deeper obscurity, for as the results of some strange accident, or a long gathering impulse of despair, he disappeared and left no sign.

This little story must strike with a chill upon anyone impatient for the advance of knowledge, and especially upon such as are inclined to assume the use of the scientific method to be synonymous with the possession of the scientific mind. Experience fully proves that this assumption is unsound, for there is no limit to the narrowness of the field within which the scientific method may be limited while the rest of the mind is uninfluenced. Even if that assumption is not maintained there are several grounds on which has been defended the proposition that a man of science does well not to traffic very freely with new ideas. It is thought that the necessary concentration on a limited problem is apt to be attenuated by the use of any general intellectual activity. A proposition more worthy of serious attention is that which declares that scepticism and suspended judgment are the very essence of the scientific mind and scarcely to be depended on too much. The conception is no doubt true when its elements are exactly defined. Without such definition these venerable phrases may very easily become mere snares; this is because they are apt to be the expression not of the principles they profess to represent but of far more deeply ingrained and potent impulses.

The mind delights in a static environment, and if there is any change to be itself the source of it. Change from without, interfering as it must with the sovereignty of the individual, seems in its very essence to be repulsive and an object of fear. A little self-examination tells us pretty easily how deeply rooted in the mind is the fear of the new, and how simple it is, when fear is afoot, to block the path of the new idea by unbelief and call it scepticism, and by misunderstanding and call it suspended judgment. The only way to the serene sanity which is the scientific mind—but how difficult consistently to follow—is to give to every fresh idea its one intense moment of cool but imaginative attention before venturing to mark it for rejection or suspense, as, alas, nine times out of ten we must do. In this traffic it is above all necessary not to be heavy-handed with ideas. It is the function of notions in science to be useful, to be interesting, to be verifiable, and to acquire value from any one of these qualities. Scientific notions have little to gain as science from being forced into relation with that formidable abstraction, "general truth." Any such relation is only too apt to discourage the getting rid of the superseded, and the absorption of the new, which make up the very metabolism of the mind.

VII.

In making this small survey of the simpler reflections that are suggested by commemorative occasions such as this, three general conceptions have presented themselves rather prominently. Some of them at least have a practical bearing, and we should therefore be very unworthy disciples of the Master we celebrate if we did not give them what point we can by a particular reference.

The first of these ideas is the familiar truth that if any human institution is looked into at all closely it is found, however admirable its ostensible purpose, to be built out of a strange mixture of elements and to comprise motives, many of them odd and some of them ugly. Memorial ceremonies show themselves to be of this class, and thereby demonstrate that they possess a thoroughly natural origin. In these mild disclosures there is nothing to dismay, and no one need be disconcerted by the homely skeletons in the cupboards of folk-lore. At the same time they perhaps have a use in explaining why the stimulation and enlargement of mind afforded by such commemorations are sometimes less potent than we could wish.

The second conception that emerges is the suggestion that with the process of time it will become increasingly difficult to separate the commemoration of the dead from the responsibility for their treatment during life, or to believe that posthumous honour is in any real sense a reparation for the dead, or a discharge of the liability of the living. It will become less and less possible to regard the discoverer of truth as responsible for the propagation of it, and charged with the duty of converting a stiff-necked generation.

The third and last idea on which our discussion has converged is that if mankind is to profit freely from the small and sporadic crop of the heroically gifted it produces, it will have to cultivate the delicate art of handling ideas. Psychology is now able to tell us with reasonable assurance that the most influential obstacle to freedom of thought and to new ideas is fear; and fear which can with inimitable art disguise itself as caution, or sanity, or reasoned scepticism, or on occasion even as courage.

We may now attempt for a final moment to link these speculations with our primary theme. In his mental environment Hunter must be regarded as a happy man. He lived in the relative intellectual freedom of the best part of the eighteenth century, before its bland sunshine had died in the smoke of industrialism, and before the French Revolution and the reaction to it had deadened speculative thought. He saw, as from a peak in Darien, the hanges, most of them involving the coronary arteries. Similar observations have been made in other countries. The statistics show that arterio-sclerosis is by o means necessarily progressive, and also that it must e curable. Seeing that the mortality figures for rterio-sclerosis are something like 6 per cent. of the otal mortality, a fraction which bears no relation whatever to the morbidity figures, it follows on the one hand that we have over-estimated the danger of arterio-sclerosis, and on the other that many cases must have recovered spontaneously. Anitschkow and his school have reported complete cures, even in severe and far-advanced arterio-sclerosis (Wolkoff).

The Clinical Proofs.

I shall confine myself to the symptoms characteristic of arterial atony.

(*a*) *Volume of pulse.*—The tonoscillogram[1] gives us a volume and pressure curve and enables us not only to determine the pressure of the blood-vessel itself apart from the blood pressure, but also the volume of the pulse. In cases of arterial atony the increase in the volume of the pulse was, in many instances, several times greater than normal. As the pulse volume cannot increase without dilatation of the blood-vessel, it readily follows that arteries must be atonic, with attenuated walls in the early stages of arterio-sclerosis. From the height of the greatest oscillation as measured at the rings of the tonoscillogram it is possible to calculate the absolute volume of the artery by introducing a so-called normal volume scale.

(*b*) *Vascular pressure.*—The tonoscillogram also shows that the vascular pressure is considerable less than the normal—a further indication of the reduced elasticity of atonic arteries. For instance, Fig. 2A shows a normal artery with an opening pressure of 24 mm. Hg, and Fig. 2B taken from an atonic artery, shows an opening pressure of only 8 mm. Hg. The tonoscillogram of a thickened vascular wall in a late stage of arterio-sclerosis shows a vascular pressure of 50 mm. Hg. Moreover, the sudden rise in the oscillation and the sharp bend at the point of maximum pressure are proof that the parting of the non-elastic wall followed as suddenly as it did in our experiments with thin-walled non-elastic tubes (prepared amniotic coating). Quite in accordance with these observations, the normal tonoscillogram (Fig. 2A) shows, besides an opening pressure curve of normal length, a uniform increase in the excursion of the oscillations; in the thick-walled artery (Fig. 2C) this increase corresponds to a drawn-out curve. In Fig. 2B, on the other hand, the oscillations rise suddenly without transitional stages and diminish with equal suddenness.

An atonic vascular system harbours serious dangers for the whole circulation. An important factor is that the air chamber action of the arteries (Otto Frank and others) is impaired. To compensate for the loss of these circulatory components the heart must become hypertrophic, and that at a stage when the capillary resistance is hardly yet increased. In this way, where the total pressure is normal or below normal, the included blood pressure can be high simply because the vascular pressure is very low.

(*c*) *Blood pressure.*—While H. Huchard regards an increased blood pressure as a regular concomitant of arterio-sclerosis, E. v. Romberg states that "in accordance with anatomical observations there is as a rule no increase in blood pressure in uncomplicated cases of arterio-sclerosis measured with the Riva-Rocci apparatus (Sawada, Groedel, Ferranini, Lukacs); only in 12·3 per cent. of the patients examined did Sawada find a moderate increase.'

I am of the opinion that in the early stages of arterio-sclerosis both high and low blood pressures can be found. The important factor is not so much the absolute blood pressure as its extraordinary instability. Occasionally variations of 50 mm. Hg and more can be observed within the space of a few minutes. Tonoscillography enables us to record graphically and to follow accurately changes in blood pressure under the most diverse conditions. If the variations are accompanied by other characteristic tonoscillographic indications, these afford further corroboration of the correctness of the diagnosis.

The stability of the blood pressure is vouchsafed by the prompt compensatory reaction of the elastic and muscular apparatus of the blood-vessels. If this apparatus is impaired, as it is in arterial atony, even the smallest demand made upon it must produce variations in pressure, which in health are readily compensated.

Further diagnostic characteristics of arterial atony can be obtained by the tonoscillographic method of measuring blood pressure, if the relation between the pressure, such as we see in the blood-vessels of the extremities.

---

[1] Plesch, J.: "Tonoscillographische Blutdruckmessungen und die Deutung der Blutdruckkurve," Abderhaldens Handbuch der biologischen Arbeitsmethoden, 1931, v., 773–844.

(5) While the arteries in a normal cadaver, true to their name, are empty, Egon Plesch found that the arteries of dead arterio-sclerotics were still filled with blood, an indication that the tonicity of the arteries, as an *ultimum movens*, was not sufficient to drive the blood into the veins.

(6) At operations the small arteries in the healthy body retract and require no ligature, while in arterio-sclerotic subjects very small arteries must be ligated.

(7) In order to prove the correctness of our contentions we conducted investigations in the Pathological Institute of the Virchow Hospital, Berlin (Prof. Anders) with apparently unchanged sections of arteries from arterio-sclerotic subjects. The sections showed the usual attenuation of the walls corresponding to their atonic state.

We inserted a cannula in a small branch of the brachial artery and so filled a ligated section of the artery, about 3 to 4 cm. in length, with a 10 per cent. solution of formalin under a pressure of about 2 metres. In order to harden the artery, we surrounded it with cotton-wool packing saturated with a solution of formalin. The filled arterial section was excised 1 cm. below the ligature to enable us to obtain a longitudinal histological preparation showing both distended and unstretched sections of the artery in uninterrupted sequence. Transverse sections of the distended and undistended parts of the artery could also be examined by this procedure. A very large number of preparations were made, but I only illustrate here the most characteristic examples.

The section seen in Fig. 1A is from a healthy body. In the undistended section of the longitudinal preparation (i.e., below the ligature) the lamina elastica interna has the regular undulating lines characteristic of contracted arterial walls in death. In the section of the artery which had been placed under pressure (i.e., from above the ligature) the undulating lines are drawn out, so that the lamina elastica forms an almost straight line.

Fig. 1B shows a transverse section of a healthy artery not under pressure (magnification × 48).

Fig. 1C shows a healthy artery under pressure (magnification × 74). The differences in the lamina elastica under the varying conditions are not pronounced; only under pressure the undulations are flattened out. The entire wall in both specimens is attenuated; this fact appears when allowance is made for the difference in magnification.

In Figs. 1D and 1E are seen macroscopically unchanged sections from a very heavy sclerotic artery. In the part not subjected to pressure (Fig. 1D) the layers of the lamina elastica interna are split up, and the individual undulations are less uniform; they are also not so marked as in the healthy artery and show a knob-like thickening at various places. In the part subjected to pressure (Fig. 1E) the undulation in some parts of the lamina elastica is obliterated, in other parts the lamina elastica is ruptured. These ruptured pieces have shrunk irregularly. The difference in the thickness of the tunica media corresponds to the dilatation of the vessel, and the tunica intima of the apparently intact artery shows the proliferation generally found in arterio-sclerotic cases.

On the whole, the preparations prove that sections from even a macroscopically unchanged artery of a sclerotic subject show pathological changes, and that the disease is not local but involves the whole system.

Ætiological Proofs.

Every influence that is capable of weakening the organism to such an extent as to produce a general atony can also without hesitation be held responsible for arterial atony and for calcification. All the ætiological factors enumerated disconnectedly in the text-books can, therefore, be brought into one system and classified.

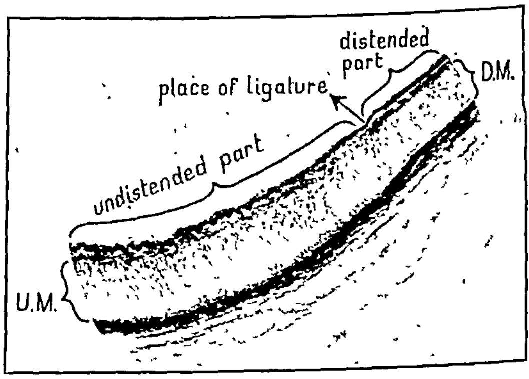
It is not my intention to enumerate every one of these ætiological moments. On close analysis they will be found to fall naturally under the simple heading of atony. Whether it is an acute or chronic infectious disease that is involved, or alimentary insults, intoxications of any description, endogenous hormonic injuries, nervous influences, alcoholic abuse or the effect of disorders of metabolism such as diabetes mellitus, gout, or obesity, it will always be found that these influences at some stage induce an atonic state, as a result of which a purely mechanical and secondary sclerosis develops in the arteries.

It is well known that arterio-sclerosis can be produced experimentally in animals by feeding them on a diet rich in cholesterol or by administering digalen, nicotine, aliphatic aldehyde, adrenalin, &c. In each of such intoxications there is a sudden excess of action that induces a state in which the tonicity of the blood-vessels is more or less seriously impaired —a state which can only with great reserve be compared with the slowly developing condition in humans. The latest idea, that spontaneous arterio-sclerosis is due to cholesteræmia, is entirely fallacious; it is probably a sequela but certainly not the cause of the calcification.

At a time when sport is so popular as to-day, I do not wish to leave it unmentioned that athletes show marked calcification by the age of 35 or 40, that they are seldom capable of great physical effort when they attain middle life, and that most of them die before they are 50. The explanation for this is quite simple; for after all heavy bodily exertions we have, by way of reaction, a severe relaxation of the blood-vessels which lasts quite a long time. The high blood pressure, meeting the arteries when in this state, produces the damage we so frequently observe in athletes.

As regards the influence of age in the ætiology of arterio-sclerosis, we must above all break away from Virchow's statement that every one has arterio-sclerosis after his fortieth year—in so far as it both expresses a threat and induces resignation. Arterio-sclerosis is not necessarily a disease peculiar to old age; it is often found in youthful people, and often absent in the aged; and when it does make its appearance in old age it rarely has any serious consequences.

FIG. 1 (A).



Longitudinal section of a healthy artery after application of a ligature. U.M. = undistended tunica media. D.M. = distended tunica media.

The Statistical Argument.

The post-mortem examination of healthy young soldiers who fell during the war revealed a surprising prevalence of arterio-sclerosis. Moenckeberg, in his very carefully prepared statistics, was able to prove that 44·5 per cent. of soldiers between the ages of 21 and 30 years and 62 per cent. of those between the ages of 31 and 40 years showed arterio-sclerotic art (Fig. 4A) the arteries have a more or less straight urse; the blood-vessels are uniformly wide and become adually narrower according to the number of branches ey send off, until finally they form a fine network of llaries with numerous anastomoses. The left ventricle is tter served with capillaries than the ght. The diameter of larger vessels comparatively small, and the walls ter resistance to the injection essure. On the other hand, in e sclerotic specimen (Fig. 4B) e arteries, in spite of the narrow conary ostium, are dilated. Besides is they show miliary aneurysmatic latations. Furthermore, the main teries, as also the arteries of the cond and third order, are lengthened d curled up like a corkscrew. The ole picture shows the arteries as un dilated vessels without resistance. tereoscopically we can see the ferences between the two preparaons still better. We will report lly elsewhere on the details obtained the above new method, which do t apply to the heart alone but also o all the other organs of the body.

(g) *The anginal condition.*—Parallel with a change in the vascular system of the heart there must be a change in its blood-supply, which not only affects the heart's capacity for work but also leads to those sensations which, according to the extent of the change, we call either oppressive feeling or angina pectoris. I believe that this theory is applicable to all forms of anginal conditions occurring in the various organs, such as intermittent claudication and dyspragia angiosclerotica, from sclerotic dizziness to epilepsy. We assume that when an artery which has lost most of its elastic resistance is over-dilated, it reacts with a hyper-compensatory spastic contraction. Within certain limits this contraction is the only effective regulator of the velocity of the blood stream. It sets in physiologically and corresponds to the dilatation that preceded it. On the other hand a pathologically changed vascular system will respond to over-dilatation with a spasm. Attacks of angina pectoris are all produced by such spastic paroxysms. It follows, therefore, that every spasm in a vascular area must have been preceded by a dilatation. The form, size, and course of the blood-vessels as shown in our pictures (Fig. 4B) justify this assumption so far as the heart is concerned. For the other organs the proofs must still be supplied by similarly injected preparations. But, even now, according to clinical experience—particularly with intermittent claudication—there is hardly any doubt that the conditions in other organs are similar to those found by us in the coronary area.

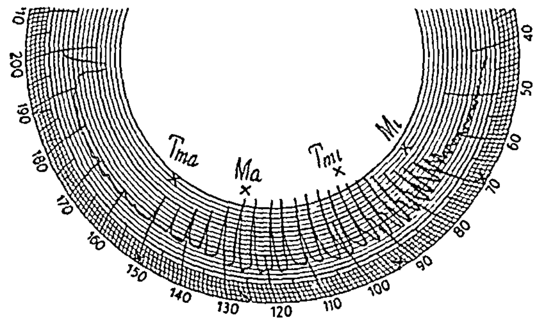
(h) *Elevated diaphragm.*—The meteorism so frequently met with in arterio-sclerotics and the high position of the diaphragm can best be explained by an unsatisfactory blood circulation in the atonic arterioles. In the intestines there is a constant development of flatus. Normally these gases are easily absorbed by the blood and reach the lungs by way of the vena cava inferior and the pulmonary arteries, where they are soon passed off in consequence of the difference in tension between the expiratory gases and the external air. Otherwise it is not possible to explain the fœtor ex ore in fermentative dyspepsia which does not emanate direct from the lungs or upper air passages. After a garlic meal the breath smells for 24 hours and more. If the circulation in the intestines is impaired, the gases remain in the intestines and inflate them. It has not yet been determined whether this increased inflation of the intestines drives the diaphragm upwards or whether the latter is elevated by suction in consequence of the raising of the respiratory middle position in individuals with weak hearts (a change which I have already reported [2]).

---

[2] Zeit. f. exp. Path. u. Ther., 1913, xiii. 1.

minimum pressure and the amplitude of the pulse be examined under varying influences (work, mechanical, thermal, and other irritations). A displacement of the values can only be caused by a rise in the maximum pressure or by a drop in the minimum pressure. The nature and the extent of the displacement are apparently of importance.

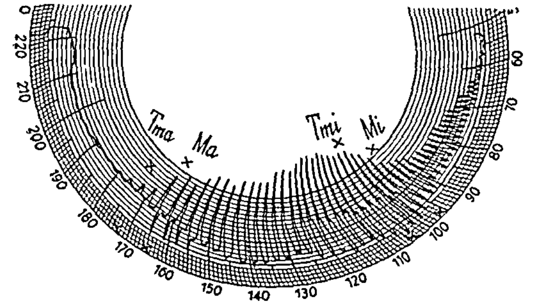
FIG. 2 (A).—*Tonoscillogram in Health.*



Total maximum pressure (Tma) = 150 mm. Hg.
Maximum pressure (Ma) = 126 ,, ,,
Total minimum pressure (Tmi) = 93 ,, ,,
Minimum pressure (Mi) = 69 ,, ,,
Opening length (Tma – Ma) = 24 ,, ,,
Compression length (Tmi – Mi) = 24 ,, ,,

(*d*) *Amount of blood.*—In the first place the blood amount serves the purpose of filling the blood channels. A dilated vascular system of necessity involves an increase in the amount of blood. The measurements I made determining the amount of blood in the system showed that in the early stages of arterio-sclerosis there is a "status plethoricus" characterised by a blood increase of up to 100 per cent. (cf. J. Plesch, *Zeit. f. klin. Med.*, 1922, xciii., 272). It is clear that in a dilated vascular system the circulation of the blood, *ceteris paribus*, must be slower. This retardation was noticed by L. Traube, and has since then been verified by more accurate methods.

FIG. 2 (B).—*Tonoscillogram of an Atonic Subject.*

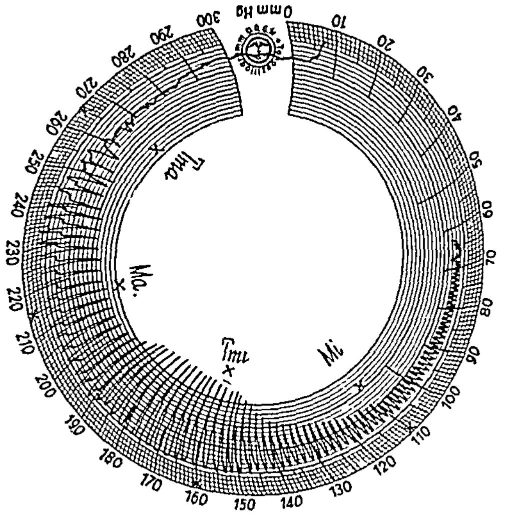


Tma = 173 mm. Hg.
Ma = 165 ,,
Tmi = 104 mm. Hg.
Mi = 96 ,, ,,
Tma–Ma = 8 mm. Hg.
Tmi–Mi = 8 mm. Hg.

(*e*) *Roentgenography.*—By means of X rays we can distinguish longitudinal and transverse atony at the aorta. In transverse atony we see the familiar picture (Fig. 3A) of the dilated aortic arch, more particularly in the ascending part of the aorta. In longitudinal sclerosis there may be a picture as shown in Fig. 3B, which up to now has received little attention. The heart is suspended from the aorta, as it were by a drawn-out elastic band, its apex burrowing deep into the diaphragm, with which its longitudinal axis forms an acute angle. It takes up a vertical position, and not a horizontal position as in transverse sclerosis. G. Holzknecht drew attention to the fact that, in cases of calcification, the left superior bend of the aorta shadow (that is, the point where the aortic arch goes over into the descending aorta) as a rule stands out more prominently as a result of the elongation of the vessel. This can be seen in Fig. 3, but on the fluorescent screen it was seen still more distinctly in consequence of the lively pulsation already observed by Holzknecht. The two types of atony can be distinguished from one another roentgenologically at a time when the vascular wall is neither thickened nor calcified.

(*f*) *Sinuous blood-vessels.*—A symptom of arterial atony that strikes the eye immediately is the sinuous temporal artery. This was always regarded as a characteristic sign of calcification, but the sinuous temporal artery is usually soft and has delicate walls. The winding course of the artery is due to the fact that it is held in a fixed position at a number of points by connective tissue, and that when the tonus of the elements working in the longitudinal direction relaxes, the artery becomes longer and then curls between the points of fixation under the influence of the blood stream.

FIG. 2 (C).—*Tonoscillogram of an Arterio-Sclerotic Subject.*



Tma = 265 mm. Hg.
Ma = 215 ,, ,,
Tmi = 160 mm. Hg.
Mi = 110 ,, ,,
Tma–Ma = 50 mm. Hg.
Tmi–Mi = 50 mm. Hg.

We are not splitting hairs when we make a diagnostic distinction between longitudinal and transverse atony, because this separation is of prognostic value. As a rule it can be said that the longitudinal atony is prognostically more favourable than the transverse. Moenckeberg was the first to draw attention to the fact that individuals with sinuous temporal arteries live longer than arterio-sclerotic subjects that have no such winding arteries. This was confirmed by Wenckebach.

Hearts with severe sclerosis and without sclerosis were, according to a technique of my own, filled with mercury through the coronary artery. The preparations so obtained in the Pathological Institute (Prof. Anders) and the Roentgen Institute (Dr. Bucky) of the Rudolf Virchow Hospital by my co-worker Dr. Egon Plesch were afterwards stereoscopically radiographed. Of the large number of photographs taken only two will be reproduced here. In the normal ing, but rather to direct it. In this way a good deal can be done to bring down excessive blood pressure to the individual level. Further than this, no direct measures should be undertaken against hypertonia. The medicaments for reducing blood pressure act by paralysing the blood-vessels and are, therefore, therapeutically absurd, because they are more inclined to help the further development of arterio-sclerosis than to prevent it. It is therefore intelligible why those remedies that produce experimental arterio-sclerosis are most effective in reducing blood pressure. When they are used, the blood pressure does well but the patient is ill. Still less rational are remedies given to "loosen the lime in the arteries." Only in the height of folly can the idea be conceived to free the body from its protecting armaments.

(b) *Reduction in the amount of blood.*—The necessary increase in the blood volume is also frequently exceeded, so that we are compelled to reduce the amount artificially. Blood-letting has most certainly celebrated its highest triumphs in the presclerotic plethora—i.e., arterial atony—and to-day it is still our most heroic remedy for this condition. If there is any objection to it, it is the brutal way in which the quantity of the blood is suddenly reduced. The atonic arteries are compelled to adapt themselves accordingly, but not without a considerable disturbance of the circulation and the exchange of body fluids. Of course, there are urgent cases in which we cannot avoid this evil, but it is more advisable to reduce the blood volume by means of a diet poor in nitrogen and salt.

We have been able to prove in a series of investigations[3] that it is possible to reduce the blood-volume far more effectively by dieting and fresh air, not only in healthy individuals and also in arterio-sclerotic subjects (vide Table). In the first few days diuresis sets in and subjective discomfort is reduced: the heart becomes quieter, the breathing freer, the head clearer, &c. If it is desired to stabilise these effects, the course must be continued for four to six weeks. A valuable adjuvant to the treatment is arsenic; I employ the old well-tried Fowler's solution. Only when arsenic is not tolerated do I give the usual phosphorus preparations.

It is practicable to repeat the nitrogen- and salt-free diet[4] every year for three to four weeks and also to introduce a "dietetic day" once a week to relieve the vascular system. This scheme has a great resemblance to certain ritual measures recommended by founders of religions (Lent, Ramadan, half and whole days of fasting, &c.), and it could therefore well be described as a Biblical diet. It has proved of value through thousands of years and requires no special recommendation. The task of medical investigation is not continually to discover this diet anew but to retain it in its original form, to set up indications for its employment and, last but not least, to investigate why it is most effective in spring. Every new adaptation of the body, whether in consequence of dietetic, physical, hygienic, or any other measures, is only of use if induced periodically. To stabilise a nitrogen- and salt-free diet simply because it has rendered good service after six weeks would be fraught with great danger and must on all accounts be avoided. It goes without saying that better results are obtainable with the dietetic fresh-air treatment if the patient has absolute mental relaxation and psychic rest.

If we had the courage to break away from pocket-book prescriptions, we should manage, in the large majority of cases, without cardiac tonics. The idea of "digitalis at all costs" is objectionable. The prolonged administration of small doses of iodide of potassium is injurious rather than useful. On the other hand, where arterio-capillary fibrosis has already developed, iodide of potassium in large doses up to 8·0 g. daily for ten days, without regard to minor complaints of iodism, is recommended. The treatment should be repeated two or three times at intervals of ten days. At the end of the dietetic fresh-air course moderate exercise and gymnastics may be allowed. Over-exertion in sport must be firmly vetoed. Cold water treatment, baths, drinking cures, and such like are subject to special indications; it would be impracticable to enumerate them all.

The symptomatic treatment is a matter of choice. Only for meteorism, as it is not so well known, I would like in conclusion to recommend tincture of asafœtida, about 15 drops in gelodurat capsules before meals.

DIAGNOSIS OF AMYLOID DISEASE
BY THE INTRAVENOUS INJECTION OF CONGO-RED.

BY J. EDGAR WALLACE, M.D. LIVERP.,
ASSISTANT TUBERCULOSIS OFFICER, LANCASHIRE COUNTY COUNCIL, LATE RIDGWAY RESEARCH SCHOLAR.

(From the Department of Pathology, University of Liverpool.)

UNTIL recent years the diagnosis of amyloid disease rested entirely on the physical findings of enlargement of the liver and spleen, together with the appearance of albuminuria in cases of prolonged suppuration. In 1923–24 Bennhold, who for 20 years had been using Congo-red as a stain for sections of amyloid tissue, discovered that the intravenous injection of this dye would disclose the presence of amyloid during life.[1] Since then the test has been investigated and the technique modified by Strasser[2] and Nathan[3] on the continent, and by Bookman and Rosenthal[4] in America, but I know of no English work on the subject.

An institution such as the Liverpool Open-air Hospital for Children, Leasowe, where there are many cases of chronic and severe suppuration, mostly tuberculous in origin, offered an excellent opportunity for a study of the test. The following is an account of the investigation undertaken.

The rationale of the work depends on the essential fact that amyloid material adsorbs Congo-red. An intravenous injection of an aqueous solution of this dye is made, and the percentage decrease of the dye-content of the plasma (or serum) over a period of one hour is estimated colorimetrically. In the normal person an amount of 10–30 per cent. is found to have disappeared. In cases of amyloid disease there is a decided increase in the rapidity with which the dye leaves the blood, and a diminution at the end of one hour of anything between 30 and 100 per cent. may be recorded.

Keith, Rowntree, and Geraghty,[5] working with Congo-red in the determination of blood volume, found that, on injection into the blood stream, it became homogeneously distributed in the plasma in four minutes and began to disappear in ten minutes. Normally all the dye had left the blood at the end of 24 hours. Smith[6] states that in normal dogs it is slowly taken up by phagocytes in various parts of the body, and that there is also a slow excretion by the liver into the bile.

Pressure from below and suction in this case work in the same direction; furthermore, these forces are here acting on an atonic diaphragm. In any case it is physiologically easier to assume that an atonic diaphragm is elevated by suction from the negative intrathoracic pressure of Donders rather than that it is raised from below by the positive abdominal pressure. The latter pressure could only be maintained by a constant tonic contraction of the abdominal walls. As a rule the intestinal gases are under minimal positive pressure (the flatus can only be expressed by a powerful contraction of both the abdominal muscles and the diaphragm!). So long as the abdominal muscles give way to the inflation pressure, the positive abdominal pressure will hardly act on the diaphragm. Moreover, if it is the intra-abdominal pressure that raises the diaphragm, the diaphragm must subside and take up its normal position again when, in the living or the dead, the abdomen is opened. In fact, however, it retains its raised position after the abdominal cavity has been opened, which proves that it is not forced upwards by the abdomen but is held up by suction.

Case No.	Weight of body in kg.	Age.	Blood pressure in mm. Hg.		Hæmoglobin.		Total hæmoglobin.		Amount of blood.		Remarks.

5A	64·0	55	224	94	15·3	11·2	586	0·91	5235	*8·2*	Arterio-sclerosis, aortic and mitr. insuff., chron. bronch. with emphysema.
5B	62·5	—	161	62	16·0	11·9	518	0·83	4360	*7·0*	Same patient examined on 8th day of NaCl and N-free diet.
6A	54 0	63	160	91	19·4	14·5	502	0·93	3450	*6·4*	Arterio-sclerosis, senile tuberculosis, chron. bronchitis.
6B	54·0	—	131	68	16·0	12·0	448	0·83	3135	*5·8*	Same patient examined on 10th day of NaCl and N-free diet.
7A	68·0	43	153	87	16·2	12·1	656	0·96	5425	*8·0*	Arterio-sclerosis, chron bronchitis, emphysema.
7B	65·0	—	133	71	18·0	13·4	644	0·99	4810	*7·4*	Same patient examined on 10th day of NaCl and N-free diet.

The conditions are therefore analogous to those obtaining in paresis or paralysis of the diaphragm. The primary cause of presclerotic meteorism is not an increased generation of gas but a reduced escape of gas. This distinction is important because of its far-reaching therapeutic consequences. Meteorism is analogous to the feeling of oppression in the heart and numbness in the legs, whilst Ortner's disease, as a paroxysm of spastic contraction of the intestinal blood-vessels, is analogous to angina pectoris and intermittent claudication. If I wished to bring these diseases unconstrainedly under the same heading, I would regard their common cause as a spasm induced by way of reaction after an over-dilatation of the corresponding atonic vascular section. In this way I dispense with the hypothesis hitherto relied on: that every paroxysm is due to an increased nervous irritability.

Therapy.

The prophylaxis and treatment of atony in its early stages consist chiefly in removing as far as possible the injurious ætiological elements. In addition, the following procedures are recommended.

(*a*) *Regulation of blood pressure.*—First of all the over-taxed circulation must be relieved. When the patient lies down the circulatory forces need only act in the horizontal direction. The exclusion of the hydrostatic pressure factor leaves only the dynamic and hydraulic pressure factor involved and immediately relieves the heart to an enormous extent. This relief is very often in itself enough to reduce the blood pressure sufficiently. A treatment for arterio-sclerosis that is not undertaken in the horizontal position must, to say the least, be regarded as impracticable, and cannot be recommended.

Superfluous as the reminder may seem, it must nevertheless be repeated and strongly emphasised that hypertonia is only a symptom and not the disease itself. Just as we no longer believe that in combating fever we are also fighting an infection, so also we may not imagine that in combating hypertonia we are doing something to relieve the arterio-sclerosis. It is of the utmost therapeutic importance, and it cannot be sufficiently emphasised, that it is only the increased blood pressure that enables us under the altered circulatory conditions to save life at all. The physician who is determined to reduce the blood pressure by force, without first combating the causes responsible for the high blood pressure, commits malpractice. The body compensates suitably in the necessary direction, but the compensation usually overshoots the mark. The most important thing, therefore, for the physician to do is not to work against compensasometimes persisted for as long as four weeks. (3) Hæmolysis and clotting spoiled a few tests. Blood containing Congo-red showed a tendency to clot rapidly. This was overcome by rinsing the tubes and syringes with citrate solution prior to withdrawal. Becker[10] has noted this effect on coagulation time, and considers that Congo-red may be of definite value as a hæmostatic. (4) Difficulty was sometimes experienced in obtaining a perfect match in the colorimeter, especially in cases of about 50 per cent. decrease. This was obviated by (*a*) reducing the stronger plasma to a known dilution with distilled water, or (*b*) adding to each plasma two drops of concentrated hydrochloric acid. This latter gave a blue coloration to each plasma which was more suitable for matching. Three readings were usually made at different settings of the standard and the average worked out. (5) In the cases recorded in Table I. as 100 per cent. decrease, Plasma II. had the straw-coloured appearance of normal plasma and the colorimeter was not used.

RESULTS.

Table I. shows that of 17 cases clinically suspected of amyloid disease, the diagnosis was confirmed by the test in 15. Six of these cases (Cases 3, 7, 9, 10, 18, and 22) were only suspected by reason of albuminuria, but the test revealed the presence of amyloidosis in the first four and its absence in Cases 18 and 22. In 12 advanced cases of chronic suppuration with no clinical manifestations of amyloid disease, the results of the test were within normal limits, as they were also in the seven cases of early surgical tuberculosis used as controls (Table II.). The three following cases of enlarged spleen of non-amyloid origin gave normal results, thus failing to confirm Strasser's observation that these cases introduce a fallacy into the test.

CASE 36.—Age 24. Spleno-medullary leukæmia. Liver normal. Spleen below umbilicus. Congo-red decrease 15 per cent. Faint trace in urine.

CASE 37.—Age 10. ? Congenital syphilis. Liver and spleen each 2 in. Congo-red decrease 28 per cent. Nil in urine.

CASE 38.—Age 10. Splenic anæmia. Spleen 3 in. Liver normal. Congo-red decrease 8 per cent. Nil in urine.

Case 39 (chronic parenchymatous nephritis) confirmed in a striking way Bennhold's statement that in this condition the dye rapidly leaves the blood via the kidneys.

CASE 39.—Age 27. Chronic parenchymatous nephritis. Non-protein nitrogen 28 mg. per cent. Blood pressure 115. Albumin 2 per cent. Granular and hyaline casts. Deficient urea concentration. Urine 27 oz. per day. Œdema and ascites. Congo-red decrease 80 per cent. Large amounts of dye present in urine 15 and 45 minutes after injection.

Further research on these lines regarding the differential diagnosis of the various types of nephritis should prove of considerable value. The test does not decide whether, in Case 39, amyloid disease was present in addition to the renal condition. The absence of dye (in any quantity) in the urines of the amyloid cases may be explained by (1) the rapid removal of dye by the amyloid material, and (2) the fact that the damage to the amyloid kidney, at any rate until the disease is well advanced, is glomerular rather than tubular. In two of the amyloid cases the results obtained by the Congo-red test were confirmed by post-mortem examination.

POST-MORTEM FINDINGS.

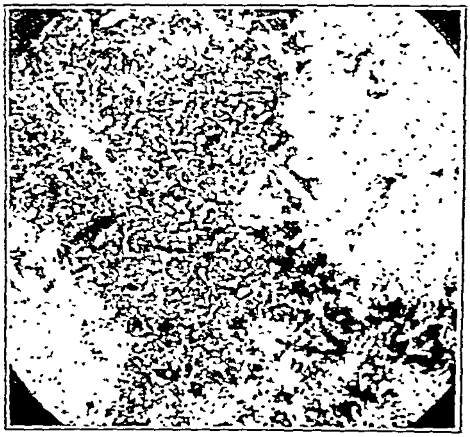
Post-mortem examinations were done on Cases 8 and 14.

CASE 8.—Autopsy two months after dye test. No macroscopic staining of organs. Advanced amyloid disease of liver, spleen, kidneys, and small intestine.

CASE 14.—Autopsy one week after dye test. Advanced amyloid disease of liver, spleen, kidneys, small and large intestines, suprarenal, and pancreas. Liver, spleen, and kidneys definitely stained red by the dye. It was found impossible to demonstrate the presence of Congo-red in the amyloid tissue on section, even after acidifying.

Congo-red as a Stain for Amyloid.—A paraffin section of the liver of Case 14 was stained by Congo-red (Fig. 2), using Bennhold's technique.[11] (Stain 15–30 minutes in 1 per cent. Congo-red. Place in lithium carbonate 15 seconds. Differentiate with 80 per cent. alcohol. Counterstain with hæmatoxylin.)

FIG. 2.



Section of liver showing (dark) areas of amyloid tissue stained by Congo-red. Normal liver cells (pale) counterstained with hæmatoxylin.

Waldensröm[12] has described a diagnostic method in which material for microscopic examination is obtained by puncture of the liver with a large-bore needle. The Congo-red method possesses the obvious advantages that it gives a quantitative result and that it is also somewhat less drastic.

Clinical observations on the above cases show that, in a certain number, healing of the tuberculous condition is followed by involution of the amyloid disease, ultimately leading to complete recovery. This view is supported by Sir Robert Jones (personal communication), Waldensröm, and Walker.[13] It is therefore of prognostic value to detect its presence and to follow its course. The use of Congo-red provides a comparatively accurate means of so doing, and the claims of this dye to a place in the clinical or pathological consideration of amyloid disease cannot therefore be disregarded.

I am indebted to Dr. T. Hartley Martin, the senior medical officer, for his kindness in facilitating the work at the Leasowe Hospital, and to Prof. J. H. Dible for his advice and assistance. My thanks are also due to Prof. John Hay and Drs. Capon, Cunningham, and Wallace Jones for permitting me to have access to various cases.

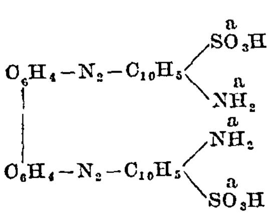
In severe cases of amyloid disease Bennhold found that the dye had often left the blood completely at the end of one hour. In only one other condition did he find a corresponding rapidity of disappearance—namely, in pure tubular or parenchymatous nephritis (four cases). Here the dye quickly left the blood via the kidneys and was found in large quantities in the urine, whereas in the normal only a trace appears in this way. In glomerular nephritis and nephrosclerosis (15 cases) he found normal values. Strasser has confirmed these findings and, in addition, points out that occasionally in cases of splenic tumour of non-amyloid origin the dye leaves the blood at a faster rate than the normal.

CHEMISTRY.

According to Mann,[7] Congo-red results from the action of tetrazo-diphenyl on naphthionic acid and has the following formula, containing two amido and two sulphonic acid groups. The red colour is changed to blue on the addition of weak acids.



The chemical nature of amyloid material is still doubtful. The old theory that it *consists of chondroitin-sulphuric acid* in combination with protein has been criticised by Eppinger and others who, on analysing masses of pure amyloid deposit, found no sulphur, phosphorus, or carbohydrate.[8] Karczag [9] states that the specific staining of amyloid depends on its strongly electro-negative charge as compared with collagen. Hyaline has a still weaker negative charge. In tissue degeneration generally the tendency is to a lowering of the charge; therefore amyloid must come from substances of strong negative character and hyaline from collagen or elastic tissue.

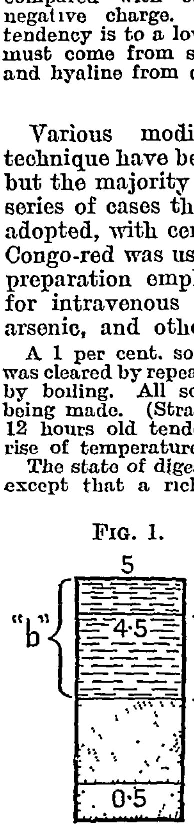
TECHNIQUE.

Various modifications of Bennhold's original technique have been made, some workers using serum, but the majority preferring plasma. For the present series of cases the method described by Strasser was adopted, with certain minor modifications. Grubler's Congo-red was used throughout, since the commercial preparation employed in chemical work is unfitted for intravenous injection by the presence of lead, arsenic, and other impurities.

A 1 per cent. solution of the dye in hot distilled water was cleared by repeated filtration through paper and sterilised by boiling. All solutions were used within 12 hours of being made. (Strasser observed that solutions more than 12 hours old tended to produce shivering attacks and a rise of temperature.)

The state of digestion in relation to the test is immaterial except that a rich fatty meal shortly before is contraindicated. The patient having passed urine, the dye was injected into a basilic vein in amounts of 0·25 c.cm. per kg. of body-weight. (The quantity for the children in the present series ranged from 6–12 c.cm.) Four minutes after injection 5 c.cm. of blood were withdrawn, preferably from another vein, and one hour after injection a second 5 c.cm. sample was taken. Specimens of urine were obtained 15 minutes and 45 minutes after injection.

FIG. 1.



Each blood sample was immediately transferred to a small flat-bottomed tube graduated at 0·5, 4·5, and 5 c.cm., which had previously been filled to the 0·5 c.cm. mark with 3·8 per cent. sodium citrate solution. The tube was filled to the 5 c.cm. mark with blood, which was then mixed with the citrate by very gentle rotation. The two tubes were then centrifuged together at 2000 revolutions for 15 minutes, by which time the corpuscular element was entirely precipitated. Two measurements (in millimetres) were then made on each tube (see Fig. 1). The height "a" from the top of the corpuscular layer to the 4·5 c.cm. mark represents the height of the plasma alone. The height "b" from the top of the corpuscular layer to the 5 c.cm mark *is that of the plasma* plus the 0 5 c.cm. of citrat originally added. This factor b/a was used in the calculatio (see below) to correct any variation in the proportion o liquid to corpuscular elements of the blood, as this pro portion is not necessarily the same in each case. The tw samples of plasma were then pipetted off and compared a Duboscq colorimeter, using Plasma I. as the standar The following illustrates the calculation in a normal case.—

		Plasma I.		Plasma II.
Colorimeter reading	..	7 0	......	8 7
b/a factor	..	22/18	......	19/16

Calculation:—

Plasma I. = 7·0 × 22/18 = 8 55
Plasma II. = 8·7 × 19/16 = 10·33

Then, if Plasma I. (the standard) be equivalent to 1 per cent., Plasma II. $= \frac{8\cdot55}{10\ 33} \times 100 = 83$ per cent.—i e., decrease of 17 per cent.

35	Hip-joint.	21

Only a *faint trace of dye* appeared in the urines.

The following personal observations on techni were made: (1) No ill-effects were seen either du or after the test. The dye was injected as rapi as the vein would take it. (2) Owing to the us difficulties with children, slight paravenous injecti were occasionally made accidentally. These w followed next day by a bright red imbibition of surrounding skin, which was quite painless, but wh may tend to be generally richer in A than the rest of England.

These findings seem quite inconsistent with the theories of Langdon Down and Crookshank. Moreover, an hypothesis was put forward by Crookshank[2] that Mongolian imbeciles were related in some way to orang-utan monkeys. As far as the blood groupings are concerned. this hypothesis finds no justification. Of the six orangs classified by Landsteiner and Miller,[8] two belonged to Group II., three to Group III., and one to Group IV. To these numbers can be added the results of two orangs tested by me: one of these was Group III. and the other Group IV. It is clear, however from such small numbers. that these monkeys, unlike the Mongolian imbeciles, show a high incidence of the character B.

To summarise, then, the distribution of the four blood groups (which is characteristic for different races) has been studied in 166 Mongolian imbeciles. The results do not support the hypothesis that this class of imbeciles has any relationship to the Mongolian race.

I am much indebted to the medical superintendents of Darenth Training Colony, the Fountain Mental Hospital, Leavesden Mental Hospital, the Mutual Sanatorium, the Manor, and the Royal Eastern Counties Institution for their permission to carry out tests on the patients at these institutions, and to the Medical Research Council and the Darwin Trust for financial assistance.

CLINICAL AND LABORATORY NOTES

NEW ANTIMONY PREPARATIONS IN THE TREATMENT OF MEDITERRANEAN LEISHMANIASIS AND JAPANESE (OR EASTERN) SCHISTOSOMIASIS.

BY G. CARMICHAEL LOW, M.D. EDIN.,
F.R.C.P. LOND.,
SENIOR PHYSICIAN, HOSPITAL FOR TROPICAL DISEASES, LONDON; DIRECTOR, DIVISION OF CLINICAL TROPICAL MEDICINE, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE;

AND

R. H. FRANKLIN, M.B. LOND.,
HOUSE PHYSICIAN AT THE HOSPITAL.

THE cases described below, one of Mediterranean leishmaniasis. the other of Japanese schistosomiasis, are recorded for two reasons; firstly, their rarity in this country makes them of interest. and secondly they illustrate the use of new antimony compounds in their treatment.

MEDITERRANEAN LEISHMANIASIS (KALA-AZAR).

A girl, aged 3½ years, was admitted to the Hospital for Tropical Diseases, London, on Sept. 24th, 1931.

Previous history.—Born in England. she was taken at the age of 4½ months to Malta where she lived for three years, then returning to England. She had never had measles, scarlet fever, or other ailments of childhood.

Present illness.—Towards the end of her time in Malta the mother noticed that the child was getting pale, was running an irregular temperature, was losing some weight, and was not making proper progress; so on arrival in England she was brought to the Hospital for Tropical Diseases.

Examination.—On general inspection the patient was noted to be very pale, was listless, looked ill and was very irritable, crying on the least provocation. The heart. lungs, and central nervous system did not show any abnormality. The abdomen was pot-bellied in appearance with protuberance of the umbilicus. The spleen was enlarged, the lower edge reaching the level of the umbilicus. It was firm in consistency and slightly tender. The lower edge of the liver was palpable, two fingers-breadth below the right costal margin and dullness extended upwards to the level of the fifth interspace in the right nipple line. There was no evidence of ascites.

Diagnosis.—On clinical grounds a provisional diagnosis of kala-azar was made, this being supported by the blood picture, which showed an anæmia, accompanied by a leucopenia. Confirmation was finally obtained by liver puncture, Leishman-Donovan bodies being found in the fluid obtained.

Treatment.—In view of the child's size and the difficulty of entering a vein repeatedly, it was decided to use von Heyden 471 (Stibosan) intramuscularly. An injection of 0·025 g. was given and as this caused no untoward results the amount was raised to 0·05 g. and then to 0·075 g., the injections being given on alternate days. By the time a total of 0·625 g. had been given. the temperature had begun to fall slightly. and there was a small but definite improvement in the child's condition. Progress, however. was not as satisfactory as one would wish, so a more potent compound—namely, Neo-stibosan—was tried and this was given intravenously. a method which proved easier than had been anticipated.

The improvement was rapid and striking. Within a fortnight after starting the intravenous neo-stibosan the temperature was normal, and with the exception of the enlarged spleen. the child seemed to be rapidly regaining good health. The spleen did not begin to decrease in size until about a week after the injections had ceased; it then became steadily smaller, but was still palpable on discharge, two and a half months after admission. The liver began to decrease in size at about the same time and was normal on discharge. The amount of neo-stibosan given intravenously was 0·075 g. per dose, at first given on alternate days but later with intervals of two days. 0·800 g. in toto being administered.

THE BLOOD GROUPING OF MONGOLIAN IMBECILES.

BY L. S. PENROSE, M.D. CAMB.,
RESEARCH MEDICAL OFFICER, ROYAL EASTERN COUNTIES INSTITUTION, COLCHESTER.

A NUMBER of different theories have been advanced to account for the occurrence of the condition known as "Mongolian imbecility." When Langdon Down [1] first described and named these cases he observed a resemblance between them and members of the Mongolian race. He further suggested that the likeness might be due to admixture of Mongolian blood among Europeans. Crookshank [2] has endeavoured to follow up this idea, supporting his contention by bringing forward many resemblances or "homologies" which he believes are common to racial Mongolians and this class of imbecile.

Owing to Landsteiner's discovery of the four blood groups, and the subsequent finding that the distribution of the four groups was fairly constant among individuals of the same race, but that it differed when groups of individuals from different races were taken, a simple test can be applied to the theories of Langdon Down and Crookshank. Quite distinct differences have been observed between Europeans and Chinese, for instance, in regard to the distribution of the blood groups, and an intermediate race, like the Russians, shows an intermediate distribution. Hence, if it could be demonstrated that English Mongolian imbeciles showed an affinity to the Mongolian races in blood group distribution, this would be very favourable to Langdon Down's hypothesis.

In order to investigate this point, 166 imbeciles from institutions in London and the eastern counties were tested. All were diagnosed as being of the Mongolian type, by common consent of the medical officers in charge of them. The grouping was carried out on these cases in the following way. A few drops of the patient's blood were taken into 1 c.cm. of normal saline containing 1 per cent. sodium citrate. Two drops of the suspension so obtained were then tested on a slide with drops of serum of Group II. and Group III. respectively. The serum was supplied by Parke, Davis and Co., from St. Mary's Hospital inoculation department. In cases where there was any doubt about the agglutination the experiment was repeated.

The following figures were obtained :—

Number of Mongolian Imbeciles of English Nationality Belonging to Each Blood Group.

I.	II.	III.	IV.	(Jansky)	Total.
65 ..	78 ..	12 ..	3 ..	..	158

In addition to these there were eight Jewish cases, of which one belonged to Group I., five to Group II., two to Group III., and none to Group IV. The question of the correct interpretation of these figures now arises.

In order to account for the proportional distribution of the various groups, Bernstein [3] advanced the theory that two agglutinogens (A and B) were inherited as dominant mendelian characters (allelomorphs), and they were both dominant to the same recessive character. His theory has met with general acceptance.[4 5] The frequencies of the two characters A and B—i.e., the probabilities of their occurrence—can be directly obtained from the distribution of the blood groups thus :

$$\text{Frequency of } A = 1 - \sqrt{(\text{I.})+(\text{III.})}$$
$$\text{Frequency of } B = 1 - \sqrt{(\text{I.})+(\text{II.})}$$

where (I.), (II.), (III.), &c., are the frequencies of the blood groups in the population studied. The frequencies of A and B are very convenient for classification of the blood groups of different races. The incidence of the character B is high in Mongolian races as compared with the incidence of A, whereas in European countries the reverse is true, A being much more common than B. Unfortunately there are no large figures available for the distribution of the blood groups among the general population of London and the eastern counties to act as a standard with which to compare the group of Mongolian imbeciles A control series of 225 non-Mongolian mental defec tives from the Royal Eastern Counties Institutio tested by the same method, however, gave th following distribution :—

Number of Control Cases Belonging to Each Blood Grou

I.	II.	III.	IV.	(Jansky)	Total.
96 ..	107 ..	15 ..	8 ..	..	226

The next table shows a number of examples of tl distribution of blood groups in different populatio for comparison with the writer's figures. They a taken from Snyder,[4] and in each case the values the frequencies of A and B have been calculated.

Distribution of Blood Groups in Different Populatio

Race and investigator.	No.	Percentage of of persons in each group.				Percent frequen of the t charact	
		I.	II.	III.	IV.	A.	
English (Mongolian imbeciles) .. .. .. (Present author.)	158	41·1	49·4	7·6	1·9	30·2	
English (non-Mongolian mental defectives) .. (Present author.)	225	42·5	47·3	6·6	3·5	29·9	
English (soldiers) .. (Hirschfeld, 1919.)	500	46·4	43·4	7·2	3·0	26·8	
Norwegians .. .. (Jewell.)	436	35·6	49·8	10·3	4·3	32·3	
Russians .. .. .. (Hirschfeld.)	1000	40·7	31·2	21·8	6·3	21·0	1
North Chinese (Pekin) .. (Lui and Wang, 1920.)	1000	30·7	25·1	34·2	10·0	19·5	2
Manchus .. .. .. (Fukamachi, 1923.)	199	26·6	26·6	38·2	8·5	19·5	2
North American Indians (pure stock) .. .. (Snyder.)	453	91·3	7·7	1·0	0·0	4·0	

It will be seen by noticing the frequencies of and B in the populations referred to in the Ta that the English Mongolian imbeciles resemble v closely the control group of English non-Mongol defectives. There is no indication here that Mongolian imbeciles are the result of crossing English with any Mongolian race, for among th the incidence of the character B is low, as in other groups of English people. The figures Jewish cases are too small to argue from, but neit do they suggest any admixture of Mongolian blo In fact, what peculiarity there is in the blood group of the imbeciles points in the opposite direction. compared with Hirschfeld's figures,[7] the proporti of A is rather high, and this appears in an excess Group II. over Group I. But a high incidence of is not uncommon in the nordic races—e.g., Scan navians—and the population of the eastern count

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE.

SECTION OF THERAPEUTICS AND PHARMACOLOGY.

At a meeting of this section held on Feb. 9th, the President, Dr. E. P. Poulton, being in the chair, Dr. E. C. Warner read a paper (by himself and Dr. A. C. Hampson) on investigation and treatment of certain cases of

Disease of Muscle and Nerve.

Some of the diseases investigated were, he said, self-limited—i.e., if left untreated the patient would recover. Others over which the preliminary research extended were, however, in quite a different category, such as progressive muscular atrophy, the trend of which was always downhill. As no hopeful line of treatment was known for this kind of case, any line which seemed to afford hope was worth careful study. Some of the conditions showed a deficiency of calcium and an excess of phosphorus in the cerebro-spinal fluid. It was not their view that those diseases were solely due to calcium deficiency, they were rather regarded from the standpoint of soil and seed.

In *chorea* there was found to be a slight diminution of blood-calcium, while in the cerebro-spinal fluid there was a 13 per cent. diminution of calcium in comparison with the figure after recovery. The C.-S.F. determination was of value in that it showed the concentration of active inorganic calcium, which might vary independently of the total serum calcium. It also indicated the degree of concentration of calcium salts bathing nerve-cells and fibres. Corresponding with the low cerebro-spinal fluid calcium values in chorea there was found to be a raised phosphate value. Preliminary results indicated that this might be due to a raised blood phosphatase. The total calcium content of the blood was not necessarily the measure of the active calcium in it; 50 per cent. of the total calcium was present in an inactive form, it could not pass through a capillary membrane nor through an artificial one. The other 50 per cent. was diffusible calcium, able to pass through a membrane; this was the only portion capable of ionisation. Important was the diffusible or ionic portion.

Probably the cerebro-spinal fluid phosphate was a measure of the active blood phosphate. A lowered calcium figure rendered the cell membrane more permeable and more liable to be attacked by toxins. Excess of phosphates in the bathing fluids would depress the ionisation of the calcium. The effect of parathyroid extract on the blood was to raise the calcium and lower the phosphate. In a recent case of parathyroid tumour the serum calcium before operation was 15·33, and the plasma phosphorus at the same date 2·2; whereas eleven months after operating on the tumour the calcium was 9·3, the phosphorus 3·6. And in a case of parathyroid tetany the condition would not have been diagnosed had not the cerebro-spinal fluid been examined.

THE VALUE OF PARATHYROID.

A valuable drug to use in bringing about a calcium rise and a fall in phosphate was Parathormone. The difficulty in its administration was the considerable difference in response of different individuals.

A boy, aged about 10, with active chorea was given parathormone. Before treatment his calcium figure was 4·7, instead of the normal 5·4. Nearly a month later, after receiving 0·2 c.cm. of parathormone twice daily, there was no improvement and no effect was noted on the fluid. For another six weeks he was given the same dosage of parathormone supplemented by calcium chloride intramuscularly, and six weeks thereafter, with the calcium at 5·7, he was completely free of his chorea.

In the resistant cases of chorea an adequate amount of vitamin D and ultra-violet light were needed. The price of parathormone—nearly 3*s.* per c.cm.—rendered it expensive for regular administration. All the subjects of chorea examined showed a heightened electrical excitability in the nerves, and responded to smaller currents than children did normally. From 75 to 80 per cent. of cases of chorea were benefited by parathormone, some of them strikingly so. In the first 20 cases the chorea ceased in four and a half weeks, on the average. A girl, aged 11, had such severe chorea that she rubbed through three sheets within 24 hours of admission, but under this treatment the chorea had gone in 16 days.

In three cases of advanced progressive *muscular atrophy* parathormone was of definite value, though in two it was of no value. Of three cases of the Werdnig-Hoffmann type, two died of intercurrent infection before treatment was begun, but the third did well. In three cases of pseudohypertrophic muscular dystrophy the findings were normal, in contrast with an instance of facio-scapulo-humeral dystrophy which had a cerebro-spinal fluid calcium value of 4·42, which improved after parathormone.

A striking result was achieved with the substance in a case diagnosed as *Schilder's encephalitis*. Its use was suggested by the low calcium and the high phosphate. The patient when seen was comatose, with white optic discs. He was aged 9, and was admitted because of involuntary incoördinate movements of arms, legs, and face. There was no heart lesion. He quickly became almost blind. His diaphragm seemed to be moving in response to his heart beat. The cerebro-spinal fluid showed no evidence of infection. The calcium and phosphate values improved, and the discs almost resumed their normal appearance and colour. It must be very rare, said Dr. Warner, for optic degeneration to recover after having been so marked.

In conclusion it was pointed out, for the benefit of anyone wishing to work on these lines, that the amounts of calcium and phosphorus dealt with were very small, requiring accurate analysis.

Dr. Hampson added that the boy with Schilder's encephalitis won a scholarship last year, at the age of 12, a good indication that the remainder of his cortex had recovered.

(*Continued from previous page.*)

extended leave from a mental hospital, suffering from a senile type of dementia. He was thought to have no syphilitic taint, the blood Wassermann reaction being negative.

Thus the exact cause of the retention which preceded rupture of the bladder was not ascertained, but it is possible that the case was one of tabo-paresis simulating the depredations of advancing years. The ulcerative nature and small size of the perforation is of interest, and also the fact that it had existed for two hours with a bladder which still contained well over a pint of fluid.

My thanks for permission to publish this case are due to Mr. Meyrick Thomas, under whose care it was admitted.

The case is of interest in that it indicates that in this case as least neo-stibosan showed itself to be much more potent than the older compound, von Heyden 471 (stibosan). Against this it might be argued that the difference in the effect was produced because the one drug was given intravenously whereas the other was given intramuscularly, but in actual fact a marked difference was noticed in the child even after two preliminary intramuscular injections of neo-stibosan had been given. Table I. gives the dosage.

After three weeks of normal temperature following the conclusion of treatment the patient was discharged from hospital on Dec. 10th, 1931, as cured, the mother being instructed to report progress in due course. The first report dated Jan. 10th, 1932, states that the progress has been maintained and that there are no signs of the disease, the child being well and happy and extremely active. On Jan. 21st the mother brought the child up for examination. She stated that progress had gone on uninterruptedly and there were no further signs of the disease. The examination confirmed this, showing a perfectly healthy little girl. The spleen had gone down very considerably since the time of leaving hospital and was now just palpable under the costal margin. There was no further distension of the abdomen, the colour of the conjunctiva and lips was perfect, and there is no doubt that the child is cured.

JAPANESE SCHISTOSOMIASIS.

Mr. B., an Englishman, aged 29, was admitted to the Hospital for Tropical Diseases on Dec. 7th, 1931, complaining of swelling of the muscles of the arms and legs, accompanied by a rash 15 weeks ago, and of general weakness.

History.—He was born in London, where he has lived most of his life. In March, 1928, went to Shanghai and remained there until October, 1931. Has always lived an athletic life and until the present condition arose has never had any serious illness. Apart from childish ailments, he had had no illness of note. No venereal disease.

Present illness.—This started at the end of July, 1931. At this time he was rowing in his spare time and was in the habit of bathing in the river and creeks afterwards. He first noticed swellings on the flexor surfaces of the arm and forearm and on the anterior surface of the thigh. These swellings were tender and were covered with a vivid red rash which felt warm but did not itch. At the time that this appeared he began to feel tired and listless and this feeling has persisted since. The rash was accompanied by evening fever, both disappearing after two or three days. Since the illness started he has lost weight, but has had no trouble with micturition or with his bowels.

A friend of his who was in the habit of bathing with him also developed similar symptoms at the same time, and was found to be suffering from *Schistosoma japonicum* infection.

State on admission.—Very pale, no signs of any rash or muscular swellings. Conjunctiva not anæmic. Systems: heart and lungs normal. Abdomen: spleen just palpable, liver edge palpable, liver not enlarged upwards. A skin test for filariasis was negative, while that for bilharziasis was positive as was also the complement-fixation test. Blood: Wassermann reaction negative. The blood count was as follows:—

Red cells ..	5,120,000	Polymorph.	35 %
White cells ..	9,400	Large mono.	4 %
Hæmoglobin ..	96 %	Lymphocytes	39 %
		Eosinophils	20 %
		Mast cells	2 %

No malarial parasites found.

Urine: no deposit: no albumin or sugar. Fæces ova of *S. japonicum*, scanty; unfertilised ascaris ova present no protozoa.

Treatment and progress.—It was decided to treat the case by intramuscular injections of neo-antimosan (Fouadin) as Khalil had reported favourably on this preparation in the treatment of schistosomiasis in Egypt. The whole course of ten injections was given in 13 days, no untoward effects were produced, and the ova rapidly disappeared from the stools. Table II. shows the amount of neo-antimosan given.

TABLE II.

Day of treatment.	Injection of neo-antimosan intramuscularly.	Remarks.
1 Dec. 15th, 1931.	1·5 c.cm.	No reaction. Few ova found.
2	3·5 ,,	—
3	5·0 ,,	Three slides examined, one ovum found.
5	5·0 ,,	No ova found.
6	5·0 ,,	Four slides examined, one ovum found.
7	5·0 ,,	—
9	5·0 ,,	No ova found.
10	5·0 ,,	No ova found.
12	5·0 ,,	—
13 Dec. 27th, 1931.	5·0 ,,	No ova found.

The patient left hospital on Dec. 28th, 1931. and on Jan. 6th, nine days later, the fæces were examined and no ova found. Since that date he has reported again saying that he now feels well and fit in every way, and that all signs of weakness have disappeared.

A CASE OF PERFORATION OF THE BLADDER.

By STEPHEN POWER, M.S. LOND., F.R.C.S. ENG.,

RESIDENT SURGICAL OFFICER, MILLER GENERAL HOSPITAL, GREENWICH.

IN the routine of emergency surgery it is not often that a strikingly unusual case occurs, and its occurrence is perhaps sufficient excuse for description, even though no great addition is thereby made to surgical lore.

A man, aged 61, was recently admitted to the Miller General Hospital with a history of having had retention of urine for several days, relieved by his doctor with a catheter. Two hours before admission he was seized with sudden acute abdominal pain following an attempt to micturate; there was no vomiting. In an attempt to correlate his story one thought at once of rupture of the bladder, but catheterisation produced 20 oz. of heavily infected urine, without emptying the organ. The abdomen wa generally tender and guarded, these features being most marked in the epigastric region where was found a veritabl diagnostic herring in the shape of a tense fatty hernia o the linea alba. The cause of this retention was not obviou since the prostate was small. Examination of the centra nervous system revealed absent knee-jerks with norma pupils.

The patient's general condition was poor, his heart bein enlarged and his arteries tortuous. However, I decide to explore his hernia under a local anæsthetic.

A sac about 1 in. long and ½ in. wide was found in th middle of the fat, and was empty. On removal some blood stained fluid could be seen in the peritoneal cavity. Th orifice being enlarged, a gush of urine expelled itself, althoug one could still feel a full bladder above the pubis. A genera anæsthetic being initiated, a suprapubic incision was mad and much urine voided from the abdomen. An ancho suture passed through the fundus of the bladder cut ou immediately and leakage had to be stopped with a purse string. Fortunately, the actual perforation was close b and showed itself to be the size of about the head of a pi surrounded by a yellowish sloughing area, and expellin gushes of urine even now. It was surrounded by a purs string. At this time the fundus of the bladder had th consistence almost of wet blotting-paper and must have bee even more attenuated before the burst. Appearances we not in the least suggestive of a traumatic rupture. Th bladder was opened and the prostate felt. There was n intravesical projection, and only a slight cleft in fron The bladder mucosa showed a foul cystitis. Proceeding were terminated by draining the pouch of Douglas and th bladder.

On the following day the patient's condition appeare to be quite good, but he succumbed within 18 hours. Post mortem examination confirmed the operative findings, an suspected condition of cardiovascular system, withou definite evidence of syphilis. It transpired that he was o

(Continued at foot of opposite page.)

died from fracture of the skull soon after admission to hospital. Her clinical history was unknown. The specimen showed :—

Coarctation of aorta just below point of entry of closed ductus arteriosus; calcification at this spot. Large anomalous vessel arising just above coarctation running to right, between the spine and the œsophagus, to supply the place of the innominate, and to form the right subclavian. Heart: slight hypertrophy in left ventricle. Aortic valves normal. Slight aortic atheroma. Vessels of both thyroid axes were large; also long thoracic and posterior scapular arteries; internal mammary arteries very large.

Mr. Harold Edwards showed a case of *Hæmolymphangioma of the Tongue* in a woman, aged 29. When two years old she had partial glossectomy for hæmolymphangioma of the tongue. The whole tongue and the floor of the mouth are now covered with growth which is at present stationary and has remained unchanged for several years.

Mr. Edwards also showed a case of *Carcinoma of the Tongue* 19 years after Whitehead's operation. A man, now aged 78, in 1913 had the right half of tongue removed for carcinoma, and 14 days later the glands on the right side of the neck removed. The pathological report on the tongue growth was squamous-celled carcinoma. No microscopical evidence of secondaries in excised lymphatic glands was found. Four months after the second operation a recurrent mass was removed from neck. The function of the remaining portion of the tongue was now excellent, said Mr. Edwards, and there were no signs of recurrence.

Dr. J. D. Rolleston showed a case of *Striæ Atrophicæ following Rheumatic Fever* in a man, aged 21, admitted to hospital on Sept. 26th, 1931, suffering from diphtheria, but found after admission to have rheumatic fever which had become complicated by endocarditis, albuminuria, and pleuropneumonia.

Temperature pursued an irregular course, oscillating between normal and 104·6° F. till Nov. 17th, the fifty-eighth day of disease, when it finally became normal. The striæ, which were situated on the back, arms, buttocks, and thighs, were first seen on Oct. 30th, the thirty-seventh day of disease. On the back they extended from the level of the lower angle of the scapula to that of the lumbar vertebræ, were transverse in direction, pinkish or livid red in colour, depressed below the level of the normal skin, and measured from 1 to 2½ in. long and about ¼ in. broad. On the left side they extended lower down than on the right, and passed round to the ventral aspect. On the buttocks and posterior part of the thighs their arrangement was longitudinal. A few faint striæ were seen on posterior aspects of both upper arms.

Dr. H. S. Le Marquand showed a case of *Suprarenal Virilism* (pubertas præcox) in a male child, aged 2 years. Pubic hair was first noticed at about the age of 14 months; since then the development of the sexual organs and general bodily growth had proceeded at an abnormally rapid rate. During the last few months his sexual proclivities had caused trouble. His parents stated that he could not be left alone with an adult woman because of the obvious sexual advances which he made; he was not attracted by small girls. These statements had been corroborated by observation in hospital.

On examination, a strong active red-headed boy, who appears to be between 6 and 7 years old. Height 3 ft. 5½ in., weight 40 lb. (average 2 ft. 11½ in. and 30½ lb.). Muscular development very pronounced, approaching the infant Hercules type. Mental development about that of a child of 2; he is exceedingly mischievous. Development of hair: pubic hair well-marked, with a horizontal upper limit; hair prominent on forearms and legs below the knee, with a lesser distribution on the back and thighs; no hair in the axillæ. Genital organs: the penis, scrotum, and testicles are well-developed, almost the size of those of an adult.

ASSOCIATION OF CLINICAL PATHOLOGISTS.

The fifth annual meeting of this association was held in the Bland-Sutton Institute of Pathology, Middlesex Hospital, on Jan. 30th, Dr. L. E. H. Whitby being in the chair.

ASCHHEIM-ZONDEK TEST.

Dr. A. F. Wright spoke of the value of this reaction in the diagnosis or exclusion of pregnancy long before this was possible by any other means; he produced figures based on his own observations and those of others showing that once pregnancy was established the reaction would, in over 97 per cent. cases, give a definite and correct answer to the question "is this subject pregnant?" His own work suggested the possibility of error in ectopic pregnancies; absent or weak reaction in a woman known to be pregnant might serve as a warning of threatened abortion. He described the method of obtaining a quick reaction by precipitating the active principle from the urine with alcohol and injecting it intravenously into a rabbit; this he had found satisfactory.—Dr. A. G. Shera asked what was the value of the test in the diagnosis of chorion-epithelioma, whether the reaction was positive as in other types of malignant disease.—Dr. S. C. Dyke said he had found the test positive in chorion-epithelioma and pointed out that the persistence of a positive reaction in a woman who had recently been confined or had aborted was strong evidence of the presence of growth of this type.—Dr. E. Wordley stated that in the absence of pregnancy he had found the reaction negative in the subjects of malignant disease, either male or female.—Dr. Wright, in reply, spoke of the necessity of cutting sections of the ovaries for microscopical examination in all doubtful cases.

BACTERIOLOGY OF NORMAL TEETH.

Dr. J. B. Davey remarked on the present tendency to attribute many rheumatic and other infections to apical infection of teeth, the streptococcus being the organism usually implicated; in support of this is adduced the fact that streptococci are practically always to be isolated from the infected apices of such teeth. He had himself isolated many such strains and had found that for the most part they were non-hæmolytic and of the type usually found in the mouth, though some might give slight hæmolysis of the α type. He described the result of examining 13 healthy teeth and 8 which would have been passed as healthy on any except the most rigorous tests; all had been removed for cosmetic or other reasons and not on account of caries or infection. From the tips of 11 of the 13 healthy teeth, and from 7 of the 8 teeth not above suspicion he had isolated streptococci. The root canal of the healthy tooth also gave a growth of streptococci.—Dr. F. B. Smith pointed out that similar findings had resulted from an investigation made some years ago by the late Prof. E. E. Glynn.

BACTERIOPHAGE IN B. COLI INFECTION.

Dr. Whitby spoke of the use of bacteriophage in the treatment of *B. coli* infection of the urinary tract. In acute cases the phage did not appear in the urine until it became alkaline, but it would often do so on the day following alkalisation, with rapid disappearance of the infection. In chronic cases the phage failed to appear in the urine at all. He pointed out that organisms which survived the initial attack of the

DISCUSSION.

The **PRESIDENT** thought the series of cases narrated were striking, though the work was still in a preliminary stage. If all refractory cases of chorea could be cured by giving parathormone and calcium salts, it would represent a great advance. He recently had a case of exophthalmic goitre in the active stage of which there was a loss of calcium. Possibly this loss might be the cause of the great weakness in these patients. The blood-calcium was 5·4.

Dr. **HAMPSON** said there was a group of people, showing clinical hyperthyroidism, with low calcium values; they had irritable nerves with low threshold for electrical stimulation. They were also those who passed into a state of tetany after operation. He thought they had parathyroid deficiency.

Dr. **N. GRAY HILL** said that at Queen Mary's Hospital, Carshalton, parathyroid was given in a number of cases of chorea, but it was an expensive preparation for institutional use; less costly methods succeeded. Some cases of chorea cleared up on nothing but rest and a quiet life, while others remained choreic in spite of any treatment. Treatments which promoted rise of blood-calcium were good for chorea. It seemed to him scarcely justifiable to take the cerebro-spinal fluid of choreic patients for examination, though if its examination was shown to be important that scruple would have to be waived. At his institution only blood examinations were made. Treatment was by diet, ultra-violet light, and calcium preparations, largely by mouth. But no two choreics followed an identical course.

Mr. **W. C. W. NIXON** said he had investigated a series of cases of eclampsia and of pre-eclamptic toxæmia of pregnancy. In two cases, in which he had obtained blood during the fits, the serum calcium was found to be between the normal limits. During the premonitory twitchings, before the actual eclamptic state, the serum calcium was not reduced. He did not assess the calcium value in the cerebro-spinal fluid, but he hoped to do so. He had given calcium gluconate, but without effect on the fits.

Dr. **P. ELLMAN** said that in 1926–27 he had investigated calcium metabolism in cases of pulmonary disease, both active and chronic; he found that the calcium content of the blood varied within the normal limits of 9 to 11 mg. He concluded that the metabolism of calcium in the tuberculous subject could be influenced by calcium and parathyroid as surely as the sugar in the urine could be influenced by a course of insulin. In a case in which the blood-calcium was low and the symptoms were active, with cough, sputum, hæmoptysis, night sweats, and loss of weight, when the calcium content had been raised to 11 the symptoms largely subsided and the patient gained in weight.

Dr. **PARKES WEBER** suggested it might be well worth while to try the effect of this treatment in recurrent angio-spastic attacks in small children, a rare condition akin to Raynaud's disease. These attacks might almost be regarded as vasomotor tetany.

Dr. **E. STOLKIND** commented on the striking result in the case of Schilder's encephalitis, especially the staying of the atrophy of the optic discs and the marked progress to recovery. Some of his own patients who suffered from encephalitis lethargica had subsequently passed Civil Service and other competitive examinations.

Dr. **DOROTHY HARE** asked whether, in view of this work, the readers of the paper would agree it was better to cease estimating blood-serum calcium, and concentrate on the cerebro-spinal fluid values, as being the more likely to afford therapeutic aid.

Dr. **HAMPSON**, in reply, said he had not worked much on the calcium content in cases of eclampsia but he had gone into the phosphate metabolism. His conclusion was that these cases belonged to group almost opposite to those now being discussed and probably parathormone would be more likel to do harm than good in them.

Dr. **WARNER**, in reply, said that as lumbar punctur was not dangerous it should be done whenever i was likely to yield results valuable in treatment There were a number of diseases which showe increased electrical excitability; Graves's disease wa one. He and his colleague did not regard paratho mone as a specific drug. They found low calciu and high phosphorus values, and they tried to recti that. The only drug which caused a rapid respon appeared to be parathormone. Its effect, howeve was not lasting, a small dose was not operative aft eight or ten hours, which pointed to the need of givi it twice daily. Perhaps after producing the ma effect progress could be maintained by other mear The striking benefit was seen in the hopeless dystroph cases, in which there was no question (as in chore of improvement if left alone.

CLINICAL SECTION.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Feb. 12 with Mr. **CECIL P. G. WAKELEY**, the President, the chair.

The **PRESIDENT** showed a patient, aged 57, w an enormous *Left Renal Tumour* which almost fil the whole abdominal cavity and was hard a craggy on palpation. There were no urinary syn toms, but there were secondary deposits in t liver, in the glands on the left side of the neck, a in both groins. A large opaque deposit could be se in a radiogram, involving the right side of the innominatum. There were no signs of second deposits in the chest, nor any sign of varicocele œdema of the left leg, in spite of the fact that tumour was of such a large size. Mr. Wakeley s that glandular deposits in renal tumours must looked upon as very uncommon.

Dr. **BERNARD MYERS** showed a case of *Milr Disease* in a woman, aged 47, who had suffered fr swelling of the right leg from infancy. All availa methods of treatment failed to cure the conditi and at present the patient was taking pituitary wh gland gr. ½ twice daily.

Dr. **TERENCE EAST** showed a case of *Coarctation the Aorta* in a man, aged 55. There were so large veins over the upper part of the sternum in t left supraspinous fossa. There were large palpa arteries with a systolic thrill and intense murm The pulses were unequal; the blood pressure, l arm, 195/145; right arm, 135/100. The heart w enlarged with extensive apex-beat, which was rat weak, the first sound being reduplicated, and t aortic second loud. The electrocardiogram was the left ventricular type, with abnormality in t T waves in the first and third leads, associat probably with the changes due to the high blo pressure. Wassermann reaction, negative. Uri normal.

Dr. East also showed a *specimen of coarctati* of the aorta removed from a woman, aged 46, w could be removed for section. Direct examination of the trachea was useful where a foreign body was present, and, recently, had also been used in diphtheria; sloughs could be removed by means of the bronchoscope, and tracheotomy or intubation might thus be avoided.

The bronchoscope was usually introduced through the laryngoscope, which was then withdrawn; the withdrawal of the laryngoscope was the only part of the examination which was likely to cause discomfort to the patient. Cough might be prevented by the application of cocaine, but it was sometimes undesirable to abolish cough. Where a foreign body had been inhaled the bronchoscope had proved invaluable in saving life, and the method should be successful in almost every case. Among the 21 cases already mentioned foreign bodies had been successfully removed in 20; the exception being an open safety-pin whose point had entered the pericardium.

The inhalation of the foreign body might cause an abscess of the lung. In one case an abscess had formed owing to the presence of a complete vertebra of a rabbit; this was removed and nine more bronchoscopic aspirations had to be performed to drain the abscess, but the patient made a good recovery. In eight other cases in the series lung abscess was secondary to the presence of a foreign body. Abscess might also follow operations, especially those on the nose and throat. If bronchoscopy were employed earlier in such cases the proportion of cures would be higher. In one case, where 25 teeth had been extracted, a lung abscess had cleared up after the removal of a piece of infected clot which was plugging a bronchus, and in another case, where 18 teeth had been removed, an abscess cleared up after two bronchoscopic aspirations. In neither case had a tooth been inhaled. It was important that bronchoscopy should not be delayed in such cases simply because radiography showed no foreign body. Of six cases of post-operative lung abscess five were cured, one two years after the operation and one a month after; one of the six was improved considerably, and later was cured by external drainage. Lung abscess might also follow pneumonia or quinsy, or might arise without apparent cause. Repeated bronchoscopic aspiration sometimes cured the patient and nearly always improved his condition so that he was fitter to stand the operation for external drainage.

In order to perform aspiration a fine aspirating tube with a gum elastic end was passed down the bronchoscope. As pus oozed from an abscess cavity granulations formed in the bronchi draining it; the bronchi normally contracted on expiration, and if they were partly occluded by granulations they were closed completely, so that postural coughing was quite ineffective in draining the abscess. With the bronchoscope in position, holding open the partially stenosed walls of the bronchi, the patient was able to cough the pus out of the abscess cavity so that it could be aspirated; the granulations could then be painted with silver nitrate.

In bronchiectasis the results of aspiration were not so good, but the patient's condition could often be improved. Direct examination made a definite diagnosis possible where new growth was suspected; in some cases it might demonstrate that only asthma or bronchitis was *present, and in a few cases the new* growth might be an innocent fibroma which could be removed.

THE ŒSOPHAGOSCOPE.

Mr. H. S. **Souttar** said that he had had considerable experience of the treatment of carcinoma of the œsophagus and, while no one could do much for the patient, it was usually possible to make him able to swallow. In order that the operator might perform the necessary manipulations an instrument with a wider lumen than Chevalier Jackson's was required, and like Mr. Negus, he used a light which threw the beam ahead. The œsophagoscope which he employed was 10, 14, or 18 inches in length, depending on the site of the growth, and the lumen was sufficiently wide to allow the tube which was to be passed through the growth to be introduced down the œsophagoscope He found it best to introduce the instrument at the angle of the mouth, with the position of the head in the normal relation to the body; as the instrument slid into the concavity of the thorax the head had to be lifted forwards and, as it passed lower down, the thorax, but not the neck, required to be straightened out. When a point was reached at which the operator saw that the œsophagus was not opening and closing with respiration he knew that the growth was under observation. Usually the tumour began to bleed, and an aspirating tube and a stream of hot water were necessary to keep the field of operation clear. Bougies with a detachable soft end were passed through the stricture, and then the lumen was further stretched by passing dilators down, threaded over the bougie. The tube to be inserted was made of closely coiled wire, about 5 inches long with a shoulder at the top and a spiral twist occupying 2 or 3 inches in the middle of its length; this spiral twist helped to keep it in position. Mr. Souttar had treated one patient who had kept the tube in position for 18 months, but the disease usually proved fatal long before that time. He had lately been treating these cases with radon seeds, placing them accurately and symmetrically in position by means of a plunger which delivered them when a button was pressed. He had been fairly successful in arresting the rate of growth temporarily, and in causing temporary regression in some cases by the use of this method. He had recently designed a new œsophagoscope by which he hoped to deliver radon seeds into the growth with still greater accuracy.

DISCUSSION.

Mr. C. **Hamblen Thomas** described two cases in which endoscopy had proved valuable. In the first, radiography had shown a brass paper clip in the thorax, but it was doubtful whether it was lodged in the lung or the mediastinum; bronchoscopy solved the doubt and the foreign body was removed. In the second case bronchoscopy established a diagnosis of bronchiectatic abscess.

Prof. J. G. **Wright** said that impaction of a foreign body in the œsophagus occurred frequently in puppies. The usual method of treatment was œsophagotomy with removal of the foreign body. In one case where the œsophagoscope had been employed the piece of bone causing obstruction was too large to be removed through the lumen of the tube. The dog was deeply narcotised with morphine and the pressure of the œsophagoscope on the larynx had been sufficient to cause death.

Mr. A. **Dickson Wright** said that he had found that in aspiration of lung abscess the amount of pus removed was small. Chevalier Jackson attributed the improvement following aspiration to the fact that the pus was so viscid that the patient would never have been able to cough it up. He thought it wise to anticipate the rupture of an abscess into a bronchus by aspirating the pus even from a closed abscess. If the case was allowed to take its course the patient was in danger of drowning in pus when the abscess ruptured. Few London hospitals had the proper equipment for the employment of endoscopic methods phage were resistant and able to propagate a resistant strain; it was therefore necessary to give a large dose of a high-titre strain. Many of the phages on the market were of low titre and should not be used until the titre had been raised by subculture with susceptible organisms; he regarded crude sewage as the best source of potent phage. Cultivation and increase of potency of the phage was better carried out at room than incubator temperature. The phage could be administered by mouth, hypodermically or locally; hypodermically he gave 2 c.cm. three times a day for three days.—Dr. **Dyke** adduced evidence in favour of the belief that so-called acute pyelitis was always associated with small abscesses in the cortex of the kidney; if this were so local instillation of the phage into the urinary passages was not a rational method of its employment.—Dr. **Cuthbert Dukes** said he had never been able to find evidence that lesions in the intestines would permit of the passage of *B. coli* to the urinary system.—Dr. D. **Embleton** stated that bacilluria was frequently associated with chronic constipation, particularly in habitual users of cascara; in such cases when the bacilluria had disappeared it could be brought back again by a dose of cascara.—Dr. **Whitby**, in replying, agreed that local instillation of the phage had little to commend it; he favoured the hypodermic route.

CONVALESCENT HUMAN SERUM.

Dr. A. G. **Signy** described his experiences in the production of immunity with convalescent human serum, with particular reference to measles. He recommended collection of blood from 10 to 14 days after defervescence, the serum being pipetted off the following day. This was tested by means of the Wassermann reaction and for sterility; all sera were then pooled and put up in ampoules with 0·5 per cent. carbolic. Such serum would maintain its potency if kept in the ice-chest for at least a year. Injection of serum within five days of exposure would prevent the disease appearing; up to the ninth day from exposure it would result in an abortive attack; thereafter it was ineffective. He drew attention to the advantages accruing from an abortive attack in the development of active immunity. Such attacks were usually so mild as not to necessitate confinement to bed. He described a method of producing an active immunity without an actual attack of the disease by injecting first a large dose of immune serum, followed 24 hours later by 1 c.cm. of blood from a case in the infective stage. He recommended a dose of 7 c.cm. for children up to 3 years of age; 10 c.cm. for older children. He drew attention to the value of convalescent serum in poliomyelitis, adding that the opportunity for its use seldom arose in this country.—Dr. J. G. **Greenfield** described the methods in use in the early treatment of poliomyelitis in Australia. Polymorph cells, he said, appear in the cerebro-spinal fluid in the early stages of the infection and before paralytic symptoms appear; they become progressively fewer as the disease declares itself. Australian experience had shown the dosage of serum was in inverse proportion to the number of these cells in the cerebro-spinal fluid.

UREA CLEARANCE.

Dr. E. **Wordley** described the Van Slyke urea clearance test of renal efficiency. This test he pointed out was regarded by its originators as an indication of the rate of clearance per unit of time of urea from the blood. It was calculated from the formula $\frac{U}{B}\sqrt{V}$ where U represents the urea in the urine, B that in the blood, and V the volume of urine secreted per minute over one hour. Where the rate of excretion of urine was high the formula $\frac{U \times V}{B}$ must be used. For the first formula a normal clearance figure was anything over 54, for the second, anything over 75. The speaker stated that he had determined the clearance figure in a number of cases and had found it to give results accurately according with the clinical condition and with the results of other tests of renal function.

Dr. **Greenfield** gave an address on the microscopical differentiation of cerebral tumours, showing specimens and slides illustrating many types of cerebral tumour. He drew attention to the clinical and histological differences between those o gliomatous and ependymal origin and described classification considerably simpler than that o Cushing, but which appeared to cover all types me with. A relatively benign and slow-growing tumou was the oligo-dendroglioma.—Prof. J. **McIntos** expressed the hope that simplification might b carried even further.

HARVEIAN SOCIETY.

A meeting of this society on Feb. 11th, with M C. P. G. **Wakeley**, the President, in the chai was devoted to a discussion on

Endoscopic Methods.

Mr. V. E. **Negus** said that the usual view was tha the bronchoscope was useful only for the removal o foreign bodies, but this was no longer the mai field in which it was employed at King's Colleg Hospital. Since 1924 the total number of patient examined by the bronchoscope for foreign body ha been 21, while in the same period no less than 36 bronchoscopic examinations had been made, on total of 95 patients, for other conditions. M Negus found that the ordinary bronchoscope wit distal illumination served all his purposes, and he di not agree with the view of some observers that th lumen was too small. The small diameter of th tube made it mobile and easy to insert; in cases o carcinoma it might be difficult to see the dist parts of the growth, but for these cases he employed modification of the instrument in which the light wa thrown ahead and not shielded. In laryngoscop he used a similar type of light. In Chevalier Jackson clinic two or three skilled assistants were require at a bronchoscopic examination, and it had bee suggested that bronchoscopy could never becom popular in England because the regular changes i the staff of resident hospital officers would mak the training of such skilled assistants impracticabl By the aid of the Haslinger head-rest, however, th surgeon could now perform the examination singl handed, and without the services of an anæsthetis Bronchoscopy was therefore the more valuable i cases where a general anæsthetic was contra-indicate Where a foreign body was lodged in the larynx th patient should be examined lying on an incline plane with his feet higher than his head; in thi position there was no danger that the foreign bod would fall into the trachea or bronchi when it wa dislodged. In children indirect examination wa often difficult, and laryngoscopy was to be preferre for example, in examining a child for papilloma o the larynx. Laryngeal growths of all kinds could b studied by this method, and if necessary a portio slender reasons, and that a certificate often meant a licence to play in the streets. When a panel patient was really ill the burden of his care fell on the hospital, and the National Insurance scheme ought to recognise that work in some quite definite way. A serious illness in a middle-class family meant a financial crisis; the voluntary hospital had instituted small paying wards, but this accommodation was far too scanty. Municipal nursing homes, like those of Scandinavia, were an inevitable step. The voluntary hospital, he said, had ceased to exist as such, and patients often complained that they could not afford to be treated in it. The only voluntary thing left was the consulting staff. If voluntary hospitals were to continue, said the speaker, let them be run on a sound financial basis, and not have to descend to the level of sending out their students dressed as nigger minstrels with barrel-organs to collect funds.

Dr. **Howard Stratford** said that the point of real difficulty in the relationship between public and private medical men lay in the clinics. It was felt by general practitioners, and also by the British Medical Association, that the basis of a national medical scheme should be the provision of the services of a general practitioner or family doctor to every individual. In emergency the family doctor and no one else was called in. Every clinic should display a large notice: "Have you a family doctor? If not get one!"

The **President** agreed that public and private doctors should hold periodical conferences. Private practitioners, he said, either singly or in combination, should start clinics for periodical examination—especially of expectant mothers—for the "better classes." These centres might reduce the incidence of rickets in well-to-do children to the low level achieved among the poor by the present welfare clinic.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

A meeting of this society was held in Manchester on Jan. 22nd, with Dr. F. H. **Lacey**, the President, in the chair.

PROLAPSE WITH STRANGULATION OF THE URETHRA.

Prof. **Leith Murray** (Liverpool), after a reference to the infrequency of a clear definition of the condition in text-books, described four cases of prolapse with strangulation of the urethra. All the patients were elderly multiparæ, their ages ranging from 67 to 84, and all had similar symptoms and physical signs—namely, considerable local pain, marked urinary frequency, especially by day, difficulty in walking, and a blood-stained discharge. He thought that strangulation of the protruding mass must occur at some stage of the process, owing to the marked livid colour, and that, although infection was present, this must be secondary. There was no tendency to urinary retention, so there appeared to be no urgency in the treatment, which consisted in the application of adrenalin and chloretone ointment for a day or two, replacement of the urethra by finger pressure (under anæsthesia in two cases), and the use of a self-containing catheter for a few days. There was no recurrence in three of the cases over a period of one to four years, but in a fragile old lady of 84 there was a slight recurrence for ten days after removal of the catheter. This was controlled by daily observation and reposition, and the patient was reported to have been free from symptoms during the last seven months.

ASCHHEIM-ZONDEK TEST IN ECTOPIC PREGNANCY.

Mr. W. W. **King** (Sheffield) described a case illustrating the value of the Aschheim-Zondek test in ectopic pregnancy in the presence of hydatidiform degeneration of the chorion. After referring to the rarity of cases in which the test could be of definite clinical value in ectopic pregnancy, he paid tribute to the support it gave in confirming the necessity for immediate operation in a difficult case.

The patient had gone 17 days over her time before the so-called period commenced, but this delay as well as certain indefinite symptoms such as pains in abdomen and left shoulder were ascribed to "chills," "over-eating," and "rheumatism" respectively. The only physical sign was the doubtful presence of free fluid, and even under anæsthesia no suspicious appendage swelling was palpable; but on arrival of a positive report on the urine, operation was insisted upon. Laparotomy showed free blood, which was mostly clotted, in the peritoneal cavity and a tubal mole which revealed naked-eye and microscopical evidence of early vesicular degeneration. The presence of this degeneration would account for the positive reaction in spite of the fact that the fœtus was apparently dead.

Mr. King referred to the greater relative frequency of vesicular degeneration of the chorion in tubal than in uterine pregnancies.

The **President** said he had found needling the pouch of Douglas helpful in the diagnosis of doubtful cases of tubal gestation.

Dr. M. M. **Datnow** (Liverpool) said he had carried out the test in three cases of tubal pregnancy, with a correct result in each case, and therefore considered it of value in arriving at a diagnosis. He believed that the reaction was never positive more than 48 hours after delivery or abortion except in cases of hydatidiform mole or where chorion-epithelioma had developed.

TWISTED HYDROSALPINX.

Mr. J. E. **Stacey** (Sheffield) showed a specimen of a twisted hydrosalpinx removed from a nulliparous woman aged 29, who had been married for four years and had complained of abdominal pain (with premenstrual exacerbations) for three years. She sought medical advice on account of sterility alone.

Bimanual examination revealed a retroverted uterus with a mass of enlarged matted appendages palpable in the pouch of Douglas, and as Rubin's test was negative a laparotomy was performed. It was found that the right tube had been converted into a hydrosalpinx 5 in. long which had undergone one complete twist and contained blood-stained serous fluid. In the process of torsion the broad ligament had been torn and there was a large hiatus in it, thus preventing the ovary being involved, but this organ was cystic and bound down by adhesions. Right salpingectomy was performed, and as the left tube was thickened and the lumen occluded at the fimbrial end, left salpingostomy was carried out, and an infected retrocæcal appendix was also removed.

Mr. Stacey discussed whether salpingostomy was preferable to a more radical operation in patients complaining of pain and sterility, and mentioned one case in which pregnancy had followed bilateral salpingostomy.

DEGENERATING FIBROID.

Dr. C. P. **Brentnall** showed a specimen of a fibroid with red and cystic degeneration, removed from a primigravida aged 27, who had complained of continuous pain and tenderness apparently due to the tumour, and present for four months. The fibroid, which was extensively adherent to omentum and colon, was almost uniformly degenerate, and showed areas of cystic degeneration containing a fluid which, after fixation, somewhat resembled chocolate in appearance. Dr. Brentnall referred to the opinion

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this society on Feb. 12th, with Dr. H. H. MILLS, the President, in the chair, was devoted to a discussion on

Public Health in its Relation to the General Practitioner.

Dr. J. B. HOWELL sketched the development of the public health movement towards the very wide ramifications of municipal health enterprise to-day. The foundation of this service was, he said, the general practitioner, and its success depended upon his capacity, competence, and clinical skill, and his training in preventive as well as in curative medicine. The practitioner in his turn depended upon the provision of the necessary facilities, and his art must keep pace with advancing science. The public medical services, so far from excluding him, gave him wide scope, being largely staffed by part-time workers. The whole of the National Health Insurance scheme was in the hands of the private practitioner; his duties under the State—particularly those of notification and certification—were wide and likely to increase still further.

Dr. Howell enumerated the facilities given to the private doctor by public medicine and the ways in which the practitioner could help the health officer. He expressed a desire for regular meetings between the practitioners and the public medical officers in each centre of population.

Dr. J. FENTON stated that at the time of the accession to the throne of Queen Victoria there had been no public health service. He outlined its history from Edwin Chadwick's work through the Public Health Acts of 1848 and 1875 until the beginning of the present century, when this country had been far in advance of all others in public health work. This work, however, had included no treatment except in fever hospitals, the primary business of which had been isolation. A desire had then arisen, he said, that public authorities should turn their attention to individual suffering; the establishment of bodies, such as the Kensington Health Society, which set up their own health centres had stimulated municipal enterprise, and infant welfare centres had multiplied. In 1914 the Government had undertaken to pay half the expenses of these clinics, which now numbered 2800. They were mainly staffed by part-time officers; moreover, before their advent the general practitioner had hardly concerned himself at all with the work which they did, for the poorest classes had not consulted doctors about the upbringing of their children. Similarly, the school medical service treated conditions in children which previously had never come to the general practitioner. School medical officers enforced the requirement that patients should first be referred to their own family doctors, but they rarely went and were rarely wanted. The tuberculosis service provided a special example of how local authorities could develop preventive medicine without encroaching on private practice. The tuberculosis clinic provided expert diagnosis, supervision of contacts, and selection of patients for sanatoriums, but did not undertake treatment; it referred to the private practitioner patients who could be treated at home. Before its establishment the poorer patients had been treated either at out-patient departments or under contract, and when they had become too ill to walk about they had entered poor-law hospitals or been treated at home by poor-law medical officers. The total expenditure on public health and social services had risen from £20,000,000 in 1891 to £348,000,000 at the present day.

THE PROFESSION UNDER A STATE SERVICE.

Dr. Fenton exhorted his audience to look at the future. A State medical service was inevitable and would come more quickly than they anticipated. The work of the doctors of the country was already very largely under the direct control of the State or the local authorities; he pointed out that hardly a member of the meeting was not employed in public medicine of some kind or another. The public hospitals in London outnumbered the voluntary hospitals in their accommodation by nine to one, and the almoners of the latter were striving day by day to get subscriptions from local authorities for special services. This tendency would be increased as the Act of 1929 was more fully operated. Moreover, he said, conditions of service under the State were better than those in private practice, just as the teacher in a State school was better paid and had better holidays than the teacher in a private school. The growth of State education had not decreased the demand for private education, and private practitioners would always be required. Practitioners who had little experience of State control feared that they would lose their independence under it; had the average general practitioner, he asked the society, more independence than their President or himself? The general practitioner worked in a very small area and had little time for research and little recreation. A public medical officer who acted with decorum and carried out his duties strictly had a measure of independence in his work which would surprise most general practitioners. The more that the profession did to help the coming of a State medical service, the more it would *do for* itself. State medicine had done much for the country; it had done more for the medical practitioner.

Dr. RONALD CARTER described his treatment of zymotic enteritis and other children's complaints at a municipal hospital. He said that "first-aid treatment" was most necessary and did not interfere with the general practitioner.

Dr. REMINGTON HOBBS asked for a closer liaison between the private practitioner, the hospital, and those responsible for postnatal treatment; this coöperation would reduce maternal mortality.

DISADVANTAGES OF STATE-CONTROLLED MEDICINE.

Sir ALLAN POWELL said that at the time of the Act of 1875 public health had been entirely a matter of sanitation; the health authorities of the country had known all there was to know about "pipes." They had then undertaken isolation, and then the treatment of the destitute, and latterly the public conscience had come to demand that the community should provide these lavish therapeutic services for all its members. He doubted whether the tendency was a good one, and pointed out the danger of teaching everybody in the country that he could have everything done for him for nothing out of the rates and taxes. He instanced some of the abuses of unemployment insurance. The greatness of the country had grown up on individual initiative, and it might not be good that all medical practitioners should be paid servants of the State with fixed salaries and holidays. The question was a most pressing one.

Dr. GERALD SLOT complained that many rheumatic heart children were certified as unfit for school for very

REVIEWS AND NOTICES OF BOOKS

Diseases of the Thyroid Gland,

With Special Reference to Thyrotoxicosis. By CECIL A. JOLL, M.S., B.Sc. Lond., F.R.C.S. Eng., Senior Surgeon to the Royal Free Hospital and the Miller General Hospital; Surgeon to the Cancer Hospital. London: William Heinemann (Medical Books), Ltd. 1932. Pp. 682. £3 3*s*.

IT is 30 years since any book dealing with the diseases of the thyroid gland and their treatment as a whole has been published in Great Britain. Mr. Joll's work has been awaited with no little interest. It fulfils the considerable expectations it has aroused, and is, indeed, a masterly presentation of the subject. The introductory chapters on anatomy and physiology are excellent summaries of an exceedingly wide field of work, and they are followed by a chapter on the parathyroids which is the only disappointing section of the book. We can only presume that the notes for it were compiled some years ago, for it contains no reference at all to hyperparathyroidism and the related cystic changes in bone, and the more recent work on calcium metabolism receives but very brief mention. Inflammatory conditions of the thyroid are well described, and the sections on endemic and sporadic simple goitre are admirable accounts, and well illustrated, of the present state of knowledge of this important subject. Relatively small space is allocated to the hypothyroid states, as is perhaps natural in a book mainly surgical in conception and scope; we could find no reference to those difficult cases of long-standing primary thyrotoxicosis in which symptoms of hypothyroidism develop at the same time. The sections of the book devoted to thyrotoxicosis are, however, excellent on the whole. Mr. Joll stresses the importance of undertaking surgical treatment sufficiently early in the disease to anticipate the visceral degeneration which inevitably occurs later, and which as well as affecting the operative risks must of necessity leave the patient with some degree of permanent disability. When considering operative results he says: "In certain countries medical opinion has for many years been so violently opposed to the operative treatment of exophthalmic goitre, doubtless as a consequence of the unsatisfactory immediate and remote results obtained by surgical measures in the first decade of the century, that patients are referred to the surgeon only when all other methods of treatment have failed and the various visceral lesions characteristic of the later stages of the disease are well advanced."

Mr. Joll's own mortality in 795 cases of thyrotoxicosis is 2·8 per cent., and he is able to show 90 per cent. of "cures" with a standard of cure which entails ability to pursue normal avocations, and, among women, the capacity to bear children without relapses. It redounds greatly to the credit of the pioneers in the surgery of the thyroid in this and other countries that what was not very long ago a dangerous operation has become in the hands of those experienced in this branch of surgery one of the safest of the major surgical operations.

Mr. Joll has undertaken no small task in dealing single-handed with the many manifestations of thyroid disease. The limitations inherent in single authorship are evident in the sections on hypothyroidism and on the cardiovascular system in thyrotoxicosis, but on the whole he has accomplished his difficult task admirably. The style is most readable, the evidence is judicially considered, and detail is never allowed to obscure principles.

The production of the book could hardly be bettered. Each chapter concludes with a list of carefully selected references and the index is worthy of the reputation of Mr. A. L. Clarke. The book should bring credit alike to author and publisher, and provides a valuable addition to British surgical literature.

A Guide to Human Parasitology

For Medical Practitioners. By D. B. BLACKLOCK, M.D. Edin., D.P.H. Lond., D.T.M. Liverp., Professor of Parasitology, University of Liverpool; and T. SOUTHWELL, D.Sc., Ph.D., A.R.C.Sc., F.R.S. Edin., Lecturer in Helminthology, School of Tropical Medicine, Liverpool. London: H. K. Lewis and Co., Ltd. 1931. Pp. 271. 15*s*.

THIS work is devoted to the animal parasites causing disease in man. Its modest title is happily chosen and indicates clearly that the work makes no claims to be encyclopædic in character. It is intended rather to set out for the benefit of the student of tropical diseases and of the qualified practitioner resident abroad the methods and essential steps by which a rapid and certain diagnosis may be reached. This question of diagnosis is kept to the fore throughout the book, and was obviously the most important consideration in the minds of the authors. They have provided clear, practical, and concise instructions in procedure; indeed, the only serious criticism which may be levelled at the work is that it tends to err on the side of brevity. Many points which may not be absolutely necessary for reaching a diagnosis, but are nevertheless essential to a true understanding of the parasite, its life-history and its effects on man, have been omitted. This is especially noticeable in the section on the protozoa, which only occupies some 50 pages as against 134 pages on helminths. This allocation of space seems disproportionately small, since under the heading of protozoa such important conditions are dealt with as amœbiasis, sleeping sickness, and American trypanosomiasis, leishmaniasis, both visceral and dermal, and malaria.

The authors lead up to the description of the parasites by giving, first, certain methods of procuring and examining suspected material, including the use of the microscope. A chapter on the spirochætacea follows, in which, it is interesting to note, the names spironema, treponema, and leptospira have been discarded, at least for the present, in favour of the first generic name spirochæta. In the mention of the individual parasites the same sequence has been used in each case: this is a great help to the reader in avoiding confusion. The generic and specific names, with the more important synonyms where any difficulty might arise, are accompanied by a paragraph giving the geographical distribution, and this is followed by a succinct account of the habitat of the parasite in the body of the host. The morphological characters are then detailed, due emphasis being placed on the more important or diagnostic features at all stages. The life-cycle is set out without a multiplicity of detail or recapitulation of divergent theories, and the pathogenicity of each organism is discussed. Finally, under the heading of diagnosis, the routine procedure for establishing the identity of any parasite is described.

At the end of the volume a number of diagrams frequently expressed that red degeneration of a fibroid in pregnancy affords no indication for operation. He had collected two series of hospital cases and found that the eleven patients who had enucleation performed. all went on to full term, while of 31 instances in which no operation was performed, one mother died of peritonitis following hysterectomy two months after delivery, and there were four abortions, one premature labour with death of the fœtus, one macerated child, and four neonatal deaths. In view of these results, of the danger of changes such as those in the specimen described, and also of the possibility of the development of sarcomatous metaplasia or dense adhesions round the tumour, Dr. Brentnall advocated early surgical treatment when red degeneration was diagnosed in pregnancy.

Prof. Leith Murray defined the late stage of red degeneration as chronic necrobiosis. or grey degeneration, and considered that all cases should be allowed to settle down under morphia unless, in spite of this treatment, there was an increase in the degree of toxæmia.

CARCINOMA OF PERINEUM.

Dr. K. V. Bailey showed a specimen of carcinoma of the perineum removed from a patient aged 36, who was single, and had complained of soreness in the perineal region for two months. Examination revealed a deep excavating ulcer of the perineum extending up to, but not actually invading the external sphincter *ani muscle*, with extensive *glandular involvement* in both groins. As a result of extensive treatment comprising three applications of radium, colostomy and excision of the left iliac and both sets of inguinal glands, and finally of excision of the ulcer, the patient had been rendered comfortable. The perineum readily healed by granulation and the glandular areas were being treated with X rays.

EDINBURGH OBSTETRICAL SOCIETY.

At a meeting of this society on Jan. 13th, with Dr. James Young, the President, in the chair, three papers were read bearing on the

Toxæmias of Pregnancy.

Prof. J. M. Munro Kerr (Glasgow) began by pointing out that little material benefit had been derived from the enormous amount of research on the toxæmias of pregnancy during the past thirty years. As Whitridge Williams had said, "it is evident that the cause of eclampsia has not been discovered, and that the peace of mind of all concerned would have been increased had many of the so-called contributors never written, or at least had withheld their contribution long enough to submit them to ordinary self-criticism."

The ætiology of the toxæmias must be looked for not when grave symptoms were present, but far back in the early days of pregnancy when, following the embedding of the zygote, great and insidious forces disturbed the normal physiological processes of the maternal organism. In the first place, there was great activity of all the endocrine glands during pregnancy, especially the *anterior lobe of the pituitary* body and the thyroid. Secondly, there was considerable destruction in the uterine mucosa at the site where the zygote embedded, and later as the placenta grew and developed, the area affected assumed large dimensions. This destruction in the early weeks was very aggressive and the deposition of tissue by the chorionic villi must result in the discharge of products of protein autolysis in the maternal blood stream. In all probability, cases of emesis gravidarum and hyperemesis were due to disturbed *metabolism resulting therefrom*. Thirdly, it had been pointed out by Snorf and Veit that portions of villi were transported by the circulation. The organism may therefore have an additional strain upon it in dealing with such foreign products. Fourthly, metabolism had distinctly altered during the first three months of pregnancy—especially protein metabolism—and although in the human subject there was seldom a definite negative phase such as was seen in the lower animals, something approaching that condition did occur. It was noteworthy that the sickness of pregnancy, the disturbances of the negative phase, and the full development of the placenta occurred about the same time.

These disturbances of the early months were succeeded by a period of relative stability lasting eight to ten weeks during which the grosser manifestations of toxæmia seldom developed, and this was followed by the last phase when outbreaks of toxæmia in one form or another were commonest. The reason for this was probably that the placenta from the sixth month onwards was a degenerating organ and the ectoderm covering the villi had almost disappeared and was more or less degenerating. It seemed inconceivable that an organ in this condition could have any activity as an endocrine organ; thus the placenta was *unlikely to produce* special hormone at this time, but it certainly acted as a store-house for such a substance. Prof. Munro Kerr thought it probable that an outbreak of toxæmia was due to products of protein autolysis; the organism already overburdened by toxins was unable to stand further strain. The pregnant woman had always a struggle to combat attacking forces—endocrine activity, digestion of the endometrium, and the resulting disturbing metabolism. *If she did not* succeed in the fight the toxins produced further infection, more especially in the liver, with the result that metabolic processes were still further affected. Renal disturbances were secondary except where any previous disturbance existed. Faulty elimination followed, and a vicious circle was created which culminated in gross toxæmia in one or other of its recognised forms.

Prof. R. W. Johnstone read a paper on a Fatal Case of presumably Acute Pregnancy Toxæmia which occurred at the seventeenth week of pregnancy and which proved fatal despite drastic operative interference.—Dr. James Davidson described a Fatal Case of Eclampsia associated with extensive cerebral hæmorrhage at the thirty-sixth week of pregnancy.

A Correction.—Dr. A. H. Douthwaite writes in reference to his remarks made at the Medical Society of London last week (p. 350). "I remarked that it was the *hyper*sthenic individual who so often suffered from gall-stones and angina pectoris, and that possibly their coincidence was as much due to the tendency of each condition to arise in the robust type, as to any ætiological connexion between gall-bladder disease and the development of coronary atheroma."

Political Speeches at Mental Hospitals.—A request by a candidate in the Irish Free State General Election for permission to address the attendants at Portrane has been refused by the Grangegorman Mental Hospital Committee on the grounds that "the holding of a meeting within the grounds of the hospital would have an unfavourable effect on the patients." Similar requests in the past have always been refused.

illustrate the life-histories of various parasitic worms; a series of tables summarise various aspects of parasitology, such as, for example, the parasites of fish, meat, and edible crustacea, and the diseases spread by the agency of arthropods. The illustrations throughout the book consist chiefly of line drawings, and, in the main, are good, because they convey an impression of the salient features on which diagnosis is based. The coloured plates might have been made much more comprehensive with advantage.

The book will be found extremely useful.

The Glycosides.

By E. F. ARMSTRONG, D.Sc., Ph.D., LL.D., F.R.S., and K. F. ARMSTRONG, B.A., B.Sc. London: Longmans, Green and Co. 1931. Pp. 123. 12*s.* 6*d.*

THIS book represents the chapters devoted to the glycosides from the authors' work entitled the "Carbohydrates and Glycosides." From now onwards this work will consist of two monographs. This one provides a masterly summary of the literature and not merely a catalogue of facts. It is written by workers who are able to give the general chemical reader a clear insight into the present position of synthetic organic chemistry in relation to this difficult field.

The most interesting sections are those which deal with modern developments. In this field, as the authors point out in the preface, the names of Prof. Robinson and of Prof. Haworth are predominant. The authors have given us a clear description of present-day views in relation to the pyranose structure of sugars; this is now to be regarded as a definitely established fact. Prof. Robinson's work on the synthesis and constitution of anthocyanins is well summarised, the main underlying principles of this work being made clear to the general reader.

The volume is a worthy addition to this well-known series of monographs on biochemistry.

Osler and Other Papers.

By WILLIAM SYDNEY THAYER, M.D., LL.D., Emeritus Professor of Medicine in the Johns Hopkins University. London: Humphrey Milford, Oxford University Press. 1932. Pp. 386. 21*s.* 6*d.*

Prof. Thayer, known to have been the closest friend of Osler, has placed Osler's name on the title page of this volume, which he commences with a series of reminiscent chapters that will be read in recapitulation or summary of a large literature; the rest of the volume is formed by a collection of addresses and papers delivered at intervals during an active professional and university life. These deliveries are interspersed throughout with comments on men and things medical which make agreeable reading. Some of the essays may be familiar to many readers such as the "Medical Education of Jones," which has certainly been published more than once before. Among the most suggestive of the papers we should place a biographical sketch of the Rev. Samuel Robert Calthrop, the interesting uncle of Lord Alverstone, Lord Chief Justice of England at the beginning of this century, who migrated to Canada, being unable to take a degree at Cambridge because he refused to sign the Thirty-nine Articles. A paper on Laennec is also excellent, and incidentally gives evidence of the real shake-up given to the medical profession in America by "Martin Arrowsmith." Mr. Sinclair Lewis's book is alluded to in more than one chapter with none of the resentment that might have been expected. Such repetitions occur in other places, and the author is aware of their presence, but they are unavoidable in any collection of public deliveries, for the pertinence of the same allusions and quotations must be present on many different occasions when the themes of the discourses are similar in many respects.

Prof. Thayer's volume displays its author as a man with a warm heart and much erudition.

Laboratories: Their Plannings and Fittings.

Second edition. By A. E. MUNBY, F.R.I.B.A. London: G. Bell and Sons. 1931. Pp. 224. With 134 diagrams and plans. 30*s.*

ANY laboratory worker of spirit who has to see to the building of a new department will no doubt take his own advice about the arrangements sooner than anyone else's. But it will be a great advantage to him to study a book such as this which goes into the details of fittings, for probably no one has ever seen all the neat devices that have been thought of, and Mr. Munby describes a number of them. The function of the book is indeed to suggest possibilities between which those responsible must choose. The book would, we think, be even more useful if it were arranged under the headlines—walls, windows, drains, and so forth, rather than under physics, chemistry, and zoology. The very important matter of making the best of the natural lighting needs fuller treatment; few realise the advantage of cutting up the windows as near the ceilings as possible.

The Genius of Louis Pasteur.

By PIERS COMPTON. London: A. Ouseley. Pp. 361. With 8 plates. 12*s.* 6*d.*

THERE are two or three satisfactory one-volume lives of Pasteur in English already—satisfactory, that is, so long as he is treated as a national hero who was, personally and scientifically, beyond criticism. This latest addition is quite unnecessary. In matter it is about as good as the others; in manner it is distinctly inferior; emotional journalism is not the best medium for the chronicles of natural knowledge.

Division Palatine.

By VICTOR VEAU, Chirurgien de l'Hôpital des Enfants Assistes. With the collaboration of S. BOREL. 1931. Pp. 568. Fr.140.

Traitement du bec-de-lièvre unilateral.

By PAUL PLESSIER, Ancien Interne des Hôpitaux de Paris. Paris: Masson et Cie. 1931. Pp. 145. Fr.30.

BOTH these books deal with the methods practised by Victor Veau in the treatment of harelip and cleft palate. They give an excellent presentation of the problem and of Mr. Veau's solution of it. Most minute descriptions of the technique are supplied, and they are illustrated by numerous and very effective line drawings. Both volumes should be of absorbing interest to anyone who undertakes this kind of work, and form an important contribution to the literature of these malformations.

BOTH these books deal with the methods practised by Victor Veau in the treatment of harelip and cleft palate. They give an excellent presentation of the problem and of Mr. Veau's solution of it. Most minute descriptions of the technique are supplied, and they are illustrated by numerous and very effective line drawings. Both volumes should be of absorbing interest to anyone who undertakes this kind of work, and form an important contribution to the literature of these malformations.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 20, 1932.

COMMEMORATION CEREMONIES.

The Hunterian Oration, with which this issue of The Lancet opens, is devised on an original plan, and this is noteworthy because over 100 of these addresses have now been delivered, centring round the personality and work of the famous man. Mr. Wilfred Trotter has written no biography whatever; he has taken it for granted that all his audience would know much of the life-history of John Hunter, and be aware of what the world owes to the learning and industry which are exemplified in the wonderful collection, the Hunterian Museum. But he asks pertinently what is the particular fitness of a commemorative oration to Hunter over and beyond the historic monument of the museum which he erected, whose orderly richness has been, and is being, steadily amplified by learned curators. And he supplies the answer, which will be a little unexpected to those who have not previously considered Hunter's work closely, but have been content to accept the estimate of him implied in the familiar cognomen of "the father of English surgery." "It is impossible," says Mr. Trotter, "not to be struck by a certain disproportion between the amount of energy and genius that was expended and the harvest of substantial knowledge that was gathered": in short, the museum, and the clinical and biological labours represented by its formation, do not tell the whole story, and the pious duty remains to supplement it from time to time.

Hunter suffered from the faults of an imperfect education and consequent inability to express himself clearly. Researches undertaken with wonderful imagination and vigour and over an enormous range did not show immediate results. The fundamental nature of the problems which he set himself to solve would anyhow have necessitated the leaving of loose ends; it would have been impossible for him to put Q.E.D. neatly after demonstrations, the objective of which could not always have been clear to himself. This will often be the disability which confronts great imaginers—their genius will be ahead of their accomplishments. In many ways the supreme Leonardo da Vinci resembled John Hunter. Leonardo's imagination was unlimited, and the difficulties which he proposed to solve in the theory and technique of art, in physiology, and in physics concerned the foundations of exact human knowledge. He was ardent and incredibly energetic, but the work which he left behind him was scanty in proportion to his efforts and his genius. And the same may be said of Hunter. Leonardo's remaining masterpieces make a small show materially when compared with the grand museum, but the museum can be regarded, when we remember the state in which it was acquired by the nation, as notes for further work. Hunter, like Leonardo, counts more as the founder of a school of thought than as the performer of accomplished work. For the rôle of pioneer the great Italian, despite the perpetual wars in the middle of which he lived, had this advantage—the Italian courts in the fifteenth century were forcing-houses of art. Very different was it with Hunter, whose period lay, as Mr. Trotter says, when there was little help for him in the general body of science, and when equipment was primitive. He carried on his researches, with only a vague idea of the nature of wound infection, and with no knowledge of histology, in a world largely indifferent to scientific research. But by his example of the way in which experiment must be tested as well as instituted, and in which knowledge must be collated as well as collected, he revolutionised the surgery of the day with enduring consequences. Hunter's own world did not know what he was doing, and it does not seem clear that he knew himself the implications of his huge labours: in his profession he was a practical success—that all men could see; but that he was one of the world's greatest philosophers escaped attention.

Towards the close of the Oration Mr. Trotter shows us the instinctiveness of commemorative rites, as displayed in the feasts of primitive tribes. Always the idea behind the primitive mind has been that by ceremony heroic virtues may be made transferable, and when the cruder methods of accomplishing this had been abandoned, it was natural to attempt to keep up the personality of the dead hero by recalling his virtues on stated occasions. But all will agree to a proposition which Mr. Trotter here puts forward that with the process of time it will be increasingly difficult to separate the commemoration of the dead from the responsibility for their treatment during life, and this will lead to changes in the pious rites. The discoverer is not responsible for the reception of his discoveries. But as the world grows wiser, new ideas cannot be received with the timidity or the opposition which have too often hitherto been their lot. The sifting of wisdom from pretence and of assumption from accomplishment will be within the power of many of the discoverer's contemporaries, and commemorative rites will then record acknowledged triumphs rather than the sadness of neglect.

X RAY PROTECTION.

The British Protection Committee, the first of its kind in any country, had to face formidable difficulties when, in 1921, it undertook the task of formulating recommendations to promote the well-being of the X ray and radium worker. Practically no published data were then available, there was no physical unit of X ray dosage, and the best that could be done was to attempt to correlate on a physical basis the practice of radiologists of standing. The recommendations were framed with

which are produced in varying degree by high-voltage equipment, and which appear to be definitely toxic.[3] There are, no doubt, many who can cite illustrations of the improved health in X ray workers resulting from improved ventilation conditions. One last point may be made. The growth in power of X ray generators makes it more than ever important to provide earthed guards and shields for high tension circuits. During the past two months alone there have been reported in the press three serious accidents, one fatal, arising from high tension shocks of this kind. This aspect is fully stressed in the revised international recommendations, especial approval being given to equipment which is completely enclosed in earthed conductors. Both the recent Paris and London radiological exhibitions showed illustrations of how such protection can be secured.

To realise the magnitude of the work which the protection committees have succeeded in accomplishing, one has only to cast back to the deplorable conditions which obtained in the average X ray department 20 years ago. There will, however, always be further work for such committees to do, if only in keeping pace with progress, and the British Institute of Radiology marked its sense of the appropriate by concluding its discussion with expressing thanks to the International and British committees for their beneficent work in the past and the hope of like services in the future.

◆

THE NURSING COMMISSION'S REPORT.

With the publication to-day of a Final Report, The Lancet Commission on Nursing concluded their labours. After 14 months' deliberation on evidence submitted, a representative group of 12 have been able to issue a unanimous report to which many specific recommendations are attached, others being implied in the text. The personnel of the Commission included matrons, physicians, and chairmen of hospitals; it included also an economist, a head-mistress, and others concerned with the careers open to educated women. It is remarkable that a body composed of elements differing so widely in outlook should have found themselves in complete agreement on points of detail as well as of principle. It would be unbecoming for us to praise the Report for its constructive suggestions, or to estimate the extent of the changes that its recommendations may help to bring about. The table of contents and the introduction, set out on p. 415, show the scope of the investigation; the Commission have not confined themselves to the enunciation of principles, but have submitted detailed proposals designed to overcome difficulties. For example, a scheme for the migration of nurses between voluntary and municipal hospitals without loss of pension rights is outlined[4]; the extension of the privilege of State registration to nurses trained in tuberculosis hospitals is shown to be possible without the addition of another Supplementary Part to the Register; a demonstration that nurses do pay indirectly, if not directly, for their training disposes of an assumption to the contrary which has had a far-reaching effect on the economics of the nursing profession. Apart from questions of professional status or economics, the Commission favour a general relaxation of discipline outside working hours, and opportunity, even encouragement, to the hospital nurse to keep up outside interests.

By a coincidence, the result of a survey on nursing education in Canada appeared in the *Montreal Daily Star* on the very day (Jan. 26th) on which the Final Report of The Lancet Commission was signed. The survey has extended over two years under a joint committee of the Canadian Medical Association and the Canadian Nurses' Association. Its terms of reference differ from those of The Lancet Commission, but some of the conclusions arrived at are on parallel lines. It is evident that the problem of combining the theoretical and practical instruction of the student nurse with her routine work, without overtiring her unduly, awaits solution in Canada as in this country. But the problem in Canada is not a shortage but an excess of nurses; one of the most significant of the recommendations made is that until such time as the demand for nurses' services overtakes the supply, hospital authorities "should aim gradually to decrease the number of student nurses by approximately 50 per cent., and to increase their staffs of graduate nurses by about 28 per cent. of the student personnel." The danger of inviting more probationers to take a nurse's training than the profession could absorb, in order to provide our hospitals with student labour, has not been ignored by The Lancet Commission. In view of the shortage of staff nurses and sisters this danger may seem remote at present in England, but in any calling unemployment will result eventually unless the number of apprentices is kept within reasonable bounds. The safeguard is outlined by the Commission—namely, the limitation of the hospitals approved as training centres to those which can provide adequate experience.

Paying Patients at Edinburgh Infirmary.—The committee of the court of contributors of Edinburgh Royal Infirmary reported against the proposal of the board of management to set aside beds for paying patients. At a meeting of the court recently, however, the proposal was supported by 27 votes to 26. One of the chief grounds of opposition was that to charge for treatment would be a departure from the 200-year "ever open door" policy of the Infirmary. Prof. Mackay stated at the meeting that in his experience half the people he had treated could have paid.

Finances of Bristol Hospitals.—A scheme to raise £250,000 in seven years for hospital extension in Bristol has been launched at a citizen's meeting, under the auspices of the Lord Mayor's Hospital Extension Fund. The recommended works are: Providing a new hospital at Winford with 100 beds; reconstructing and enlarging the Eye Hospital; providing additional accommodation at the Royal Infirmary for cancer patients, and extra beds at the General Hospital; adding an out-patient department and new home for nurses to the Children's Hospital; enlarging Winford Orthopædic Hospital; providing sun-balconies, children's wards, altering and enlarging the out-patients' department at the Homœopathic Hospital. Last year 130,000 patients were treated in Bristol Institutions.

regard, on the one hand, to the safety of the operator, and, on the other, to the desire not to cramp progress. The Committee's efforts received the sympathetic coöperation of the British industry, without whose support little could have been effected. There has been no question of legalising these recommendations, but the Ministry of Health, the Ministry of Pensions, the Board of Trade, the Home Office, and H.M. Office of Works, among others, took cognisance of the Committee's work. As time went on, the recommendations needed to be modified here and there in the light of experience. At first protective devices tended to be heavy and clumsy, and excited much criticism on that score, but presently it was realised that these objections could be met by mounting the protective container close to the tube; thus the self-protected X ray tube came into being, its protective value conforming to the British figures. From the outset too the Protection Committee invited and received the coöperation of the National Physical Laboratory which has tested many kinds of protective materials, and has inspected several hundred X ray departments in all parts of the British Isles, thus giving valuable and wide-spread effect to the Committee's work. At Stockholm in 1928 the British recommendations were adopted by the International Congress of Radiology which at the same time set up an International Protection Committee with Dr. G. W. C. KAYE and Dr. S. MELVILLE as honorary secretaries. The effect of this action was profound; for whereas at Stockholm protective devices were scarcely found outside the British section, three years later in Paris they permeated the entire exhibition and had clearly become a world-wide routine.

The international recommendations represent an attempt to embody an ideal. The Committee aimed at main principles and simplicity rather than detail, and the recommendations have come to serve as a connecting link between countries which have formulated national recommendations in greater detail to suit their own requirements. Among these are Austria, Czechoslovakia, Denmark, Germany, Greece, Holland, Hungary, Italy, Norway, Russia, Spain, Sweden, Switzerland, and the United States. In every case the major principles are maintained, some of them are more drastic in detail than the international code, some have been given legal effect. These various national recommendations have recently been collected and compared by the League of Nations Health Organisation in a comprehensive brochure[1] by Dr. H. WINTZ and Dr. W. RUMP, of Erlangen. While little or no recognition is given in this treatise to the pioneer part this country has played, it would be ungenerous not to bestow high praise for its thorough and critical treatment of the main issues. Radiation protection, electrical protection, fire protection, and hygienic measures are discussed, and the inference is unmistakable that the international recommendations are reasonable and practical. Reference is made to the work of medical investigators in different countries who have made estimates of the tolerance dose in terms of the international unit; they are all of the order of 10^{-5} r per second. There is good agreement as to the lead-absorption curve of X rays, making it possible to correlate the tolerance dose with the lead protection proper to different conditions. The results are a close confirmation of the protection figures adopted by both the British and the International Committees. The bibliography of original papers, containing between 500 and 600 references, bears ample testimony to the world-wide interest which the subject has excited.

The international, in common with many of the national, recommendations refer to the value of periodic blood examinations in order to reveal the physical condition of an X ray or radium worker—a precaution fully endorsed at a recent meeting of the British Institute of Radiology. If it could be arranged for the records of such examinations to be collected and digested by some central body, the results would be of great service to the International Committee when they next confer. In the case of radium workers, periodic clinical and blood examinations are regarded as vital by the Radium Commission. There has been a certain amount of misunderstanding as to the degree of protection that the walls of X ray rooms should provide against scattered radiation. The international recommendations make it plain that when a modern self-protected tube is used additional protection on the walls is often not necessary, except perhaps in the region of the operator or in the direction of the beam. If the walls are of 9 in. brick or concrete, the lead equivalent is about 2 mm., which means that normally no additional protection is anywhere necessary. The fact that masonry walls may be adequately protective in themselves is sometimes lost sight of and unnecessary demands for additional protection are occasionally made by radiologists and architects. On the question of ventilation it does not appear always to be realised how moderate is the international recommendation of ten changes of air an hour. The Home Office has published the results of exhaustive inquiries on the subject,[2] the values recommended for various types of occupation ranging from 6 to 30 changes an hour. The value adopted by the International Committee is only half as much again as the figure given as the minimum. As an illustration, the ventilation requirements for a room as large as 25 × 20 × 11 ft. high may be met by the smallest propeller fan normally fitted—namely, one of 12 in. diameter. The outlet however must be in the right place and the inlets big enough and properly distributed. There need then be no draughts, and the fresh air, adequately warmed, of course, will dispel the sense of weariness and lassitude so common in X ray departments. This langour is claimed to be largely associated with the presence of traces of ozone and nitrous fumes, which are produced in varying degree by high-voltage equipment, and which appear to be definitely toxic.[3] There are, no doubt, many who can cite illustrations of the improved health in X ray workers resulting from improved ventilation conditions. *One last point may be made.* The growth in power of X ray generators makes it more than ever important to provide earthed guards and shields for high tension circuits. During the past two months alone there have been reported in the press three serious accidents, one fatal, arising from high tension shocks of this kind. This aspect is fully stressed in the revised international recommendations, especial approval being given to equipment which is completely enclosed in earthed conductors. Both the recent Paris and London radiological exhibitions showed illustrations of how such protection can be secured.

ANNOTATIONS

ASBESTOS IN LONDON TUBE RAILWAYS.

IF it be true that asbestos fibre was woven into cloth and used in ancient Rome, the medical profession has been negligent in its failure, until quite recently, to detect the existence of chronic industrial pulmonary asbestosis. The first fatal case of pulmonary asbestosis was recorded by H. M. Murray in 1900, and a full account of the disease was given two years ago in our own columns[1] by Dr. W. B. Wood and Dr. S. R. Gloyne. The Home Office inquiry into the effects of asbestos dust on the lungs, published shortly afterwards,[2] has been followed by the adoption of active measures to suppress dust in asbestos factories. In many such factories the introduction of exhaust ventilation and the replacement of dry processes by wet have changed the atmosphere in which the work is carried out until it is now free at least from visible dust. The operation of cleaning the carding machines by steel brushes, undoubtedly a potent source of fatal pulmonary asbestosis, has now been replaced by a vacuum method. In view of the fact that the dust particle producing the lesion in the lung has a diameter of only 2 μ to 10 μ it is obvious that the dust must be suppressed at its source; the use of respirators is futile. Illustrations were recently given in the daily press of an experiment which has been devised to coat the London tubes with asbestos in an attempt to minimise noise. In these illustrations the workman was provided with a double projector, fitted with triggers by which he released from two independent jets a spray of pulverised asbestos, apparently under considerable air pressure, and a spray of some adhesive solution. According to the illustrations the asbestos powder passed through the atmosphere for something like six inches before meeting the stream of adhesive. Though it is true that the workman was provided with a mask, it is equally true that his clothing was covered by asbestos powder. Experience in asbestos factories would indicate that, should the experiment of the London tube railways lead to an extensive use of this method for deadening noise in all the underground railways of London, then a large increase in industrial pulmonary asbestosis may be expected in years to come. In the House of Commons last week (see p. 374) Dr. W. J. O'Donovan asked the Home Secretary if adequate precautions had been taken to prevent fatal lung disease in workers lining London tubes with asbestos. Sir Herbert Samuel replied that he had no powers of control in respect of this work under the Factory or other Acts, and had no information at present as to the precautions taken. But he promised to make inquiries.

HIGH BLOOD PRESSURE AND STROKES.

DESPITE much investigation since Allbutt's original description of high blood pressure there is still doubt about its cause and symptoms, especially in the earlier stages. It is, as a rule, only later on, when the condition is fully developed and grave symptoms have supervened, that patients with hyperpiesis are seen and studied by the specialist. Since by then irreparable damage has been done, it is to earlier recognition and study that we must look for advance in our knowledge. The condition is so common as to be an ideal subject for study by the general practitioner, and in an essay awarded the Sir Charles Hastings clinical prize for 1930, Dr. H. O. Gunewardene[1] records observations and conclusions on the "sudden severe attacks" affecting the nervous system that are met with in this disorder. He finds that minor paralytic and sensory phenomena are more common than the major apoplectic fit associated with a severe cerebral hæmorrhage. These minor attacks may be either permanent or transient, and their duration is sometimes only a matter of minutes or hours. In distribution they may be hemiplegic, monoplegic, or localised to one part such as the ey or tongue. The sensory phenomena are similar t the motor in distribution, and take such form as paræsthesia, numbness, pain or blindness Dr. Gunewardene finds that severe cerebral hæmorrhage is rare in patients whose diastolic pressure i less than 135, whereas the less severe strokes occu with diastolic pressures of between 115 and 125, n case being seen with a diastolic pressure less than 11 His observations also show that cerebral hæmorrhag is unusual in patients under observation who hav been warned to lead a quiet and restricted lif whereas fatal hæmorrhage is likely in patien carrying on their normal occupation and making n allowance for their hypertension. He also mak it clear that both fatal cerebral hæmorrhage an transient strokes are very uncommon once cardi failure has begun or there is clinical evidence cardiac enlargement.

RESULTS OF GASTRECTOMY FOR CANCER

IN a communication[2] to the Academy of Medici on Jan. 19th, Prof. H. Hartmann reviewed the la results in 125 cases of gastrectomy for cancer of t stomach, observed for periods ranging up to years. Of the 25 patients who showed no sign relapse, all but one had been under observati since the operation for periods varying between 1 a 27 years. There were, further, seven patients w had died, but not of cancer, and these deaths h occurred from 3 to 19 years after the operati Another group included 13 patients, the cause whose death from 2 to 13 years after the operat was not known; there may, perhaps, have b some deaths from recurrence of the disease am these 13. Lastly, there were 80 patients, wh death was due to recurrence of the disease, in cases during the first year, in 35 during the seco in 8 during the third, and in 6 during the fou year after the operation. Altogether 39 patie (or 31 per cent.) survived the operation by three ye or more, and Prof. Hartmann is inclined to put 29 or 30 per cent. the proportion of his patients whom a cure could be claimed. He has achie this comparatively successful result, not so much sacrificing the greater part of the stomach, as removing with the greatest care the groups of gla which are most subject to invasion. He arg that even better results would certainly follow ear diagnoses and operations performed before the dise had extended beyond the first relay of glan His conclusion that "le cancer de l'estomac est bon cancer au point de vue opératoire" is m encouraging. His communication would, however, have been still more interesting had he stated how many other cases of cancer of the stomach he had observed in the same period and had not operated on for some reason or other. In the discussion following this communication, Prof. Chauffard gave support to his scepticism as to operative cure of cancer in general by recording the case of a woman who died at the age of 92, when cancer developed in the scar of an operation for cancer of the left breast more than 50 years earlier. Had she died at the age of 91, she would have been cited as an irrefutable case of cure of cancer by operation. This point is, perhaps, of academic rather than practical interest; most patients operated on for cancer would not be greatly perturbed by the prospect of the disease recurring 50 years later.

PHYSIOLOGY OF WEEPING

It is well known, at any rate by mothers, that infants do not shed tears until they are several weeks, or in some cases months, old. Darwin observed the fact and comments on it in his book on "The Expression of the Emotions in Man and Animals." Mr. Treacher Collins, in a recent article,[1] explains that this is not because the lacrymal glands are not developed at birth but because weeping is not a reflex action in the ordinary sense, but rather a conditional reflex analogous to the secretion of the salivary gland that may be excited by the sight or even the thought of food. Weeping, in fact, is a late physiological development, both in the individual and in the race. In spite of legends about elephants or crocodiles, it seems to be established that no animals except man do actually shed tears. Mr. Lindsay Johnson experimented on crocodiles by squeezing the juice of an onion mixed with common salt into their eyes but obtained no confirmation of the myth. The physiological importance of the lacrymal secretion in man is in the first place that it keeps the surface of the cornea well lubricated and free from minute particles of dust, and in the second place that its most important constituent, lysozyme, acts as a very efficient bactericide. This is the function, not of the excessive secretion known as weeping, but of the ordinary constant secretion which may be increased by reflex action following upon any irritation to the cornea. So important does Mr. Collins consider it that he suggests that the immunity of infants from ophthalmia neonatorum in whom Credé's treatment has been employed at birth is more probably due to the lysozyme in the lacrymal secretion than to any germicidal property in the very dilute solution of nitrate of silver employed. For although the lacrymal glands of the young infant do not react psychically they do react reflexly to any ordinary stimulus and the instillation of drops acts as such. Mr. Collins goes on to consider the other protective mechanisms of the eye and especially the firm closure of the lids which is often associated with weeping. This is effected by the orbicularis oculi muscle and especially by certain fibres of it situated near the conjunctival surface of the lid and known as the "muscle of Riolan," which are found to be much more highly developed in man than in any other mammal. The effect of tight closure of the lids is to protect the ocular blood-vessels from the effect of any sudden increase of blood pressure due to extraordinary expiratory efforts with a closed glottis. It is Nature's corrective to the sudden suffusion of the blood-vessels of the eye which attends any violent muscular effort, especially if the jugular veins are at the same time compressed by a tight collar. In this connexion, Mr. Collins mentions the relief that may sometimes be given to a tendency to subconjunctival hæmorrhages by changing the habit of wearing tight collars, also the rationale of bandaging the eyes after any eye operation involving an opening into the globe.

ASPHYXIA NEONATORUM.

THE methods of peripheral stimulation formerly employed to encourage respiration in the newly born—such as smacking, pinching, and cold-tubbing—have now been abandoned because it is realised that the necessary stimulus is almost certainly chemical rather than physical. But it is still by no means certain exactly what this stimulus may be. Many have held that an increased carbon dioxide tension of the blood reaching the respiratory centre is the operative factor, and on the analogy of the successful use of carbon dioxide in the treatment of carbon monoxide poisoning (where the tension of both CO_2 and oxygen in the blood is low) Yandell Henderson has consistently and eloquently pleaded the value of CO_2 in stimulating respiration in the newly born. From an extensive study of the fœtal blood, however, N. J. Eastman[1] now calls the rationale of this method of treatment in question. He finds that in asphyxiated infants the blood shows a greatly increased CO_2 tension and a serum pH reduced to the lower limits compatible with life, and he argues that the administration of CO_2 to stimulate respiration in such cases is not only valueless but actually harmful. He regards the primary blood chemical change as a reduction in the oxygen content of the fœtal blood, and emphasises that the chief therapeutic indication is therefore for oxygen. Of the simpler methods of filling the lungs with air, manual artificial respiration and mouth-to-mouth insufflation are those most readily available; it should be recognised, however, that neither is without danger, since ribs may easily be fractured by rough handling and the lung or stomach ruptured by too vigorous insufflation. Oxygen may also be given directly by mask or nasal catheter, and probably the ideal method would be a combination of the former with artificial respiration carried out by a Drinker respirator, which was described in THE LANCET last year (1931, i., 1186).

ERYTHEMA NODOSUM.

THE causation of erythema nodosum has long perplexed students of the disease, the main views on its origin at the moment falling into three groups. First there is the theory of those who, impressed by the association with tuberculosis which has been noticed by many workers, particularly in Scandinavia, regard the eruption of erythema nodosum as the exanthem of tuberculosis. Then there are those who, while recognising the association between tuberculosis and erythema nodosum, realise that this association is by no means constant and are therefore led to believe that the disease is an acute specific fever—"nodal fever." Finally, there are those who look on erythema nodosum as an allergic manifestation which may occur in allergic states due to various sensitising agents. Its association with tuberculosis they explain by the fact that the tubercle bacillus is a common allergen, as evidenced by the frequency with which a positive tuberculin reaction is found amongst the general population. Dr. W. R. F. Collis[1] has recently produced strong evidence in support of this view. In a study of eight children suffering with erythema nodosum, five were found to be definitely tuberculous by history, clinical findings, positive Mantoux test, and in three cases by the discovery of tubercle bacilli in the stomach wash-out. The remaining three cases however presented no evidence of tuberculosis and the Mantoux test was negative in all. But these three cases gave a strongly positive reaction to an intradermal injection of hæmolytic streptococcal endotoxin, a reaction which closely resembled the nodes of erythema nodosum itself. These three cases followed acute streptococcal sore-throats in from 5 to 20 days. Dr. Collis's work makes it clear that erythema nodosum is neither a specific disease nor invariably tuberculous in origin, but that the eruption is the result of the action of the soluble products of certain organisms on tissues already hypersensitive. It is thus possible that it may occur in other infections besides those due to the tubercle bacillus and hæmolytic streptococci.

THE SCHÜLLER-CHRISTIAN SYNDROME.

THE association of growths in the membrane bones of the cranium with diabetes insipidus and exophthalmos was first ascribed to some form of dyspituitrism, but of recent years the tendency has been to place it in the group of general metabolic disorders. In this group there are already such maladies as Gaucher's disease in which the chemical disturbance appears to affect kerasin, the Niemann-Pick disease in which phosphatide is incriminated, and perhaps here should be included a curious form of hepatic enlargement associated with excessive deposition of glycogen as described by Gierke.[2] In a recent account[3] of an example of the Schüller-Christian syndrome by Dr. R. Attig of the University Children's Clinic in Berlin, the author refers briefly to these other defective storage diseases before proceeding to describe his case under the title of generalised xanthomatosis, cholesterol being cited as the chemical substance affected in this condition. The patient was a boy of 3½ years who had been perfectly well until a year previously when he fell out of bed and three weeks later developed a tumour in the neighbourhood of the left temple with protrusion of the left eyeball. The exophthalmos became less in the next few weeks but the bony tumour remained stationary. Shortly afterwards the boy was noticed to be limping with his left leg and about a year later a swelling appeared at the root of the nose which led to his coming under hospital observation. Swellings were found on the skull in several situations and radiological examination showed the curious areas of defective bone described by Christian as giving a moth-eaten appearance to the picture and by Attig as being like a map. Changes were also found in the left iliac bone. The blood cholesterol was raised to 244 mg. per 100 c.cm. and on the skin of the back between the shoulder-blades there were numerous small papules of varying size and of a reddish-brown colour. The swelling in the neighbourhood of the glabella was punctured without result and a small piece was removed for section. It was of a definitely yellow tint and on examination showed the large foam-cells, characteristic of the disease, which contained a substance doubly refractive to polarised light. The histological examination indicated that the tumour was a xanthoma. While the child was in hospital the tumours in the scalp got bigger while the skin condition became more widespread and numerous punctiform hæmorrhages also appeared in the skin. Death occurred four months after admission and post-mortem examination confirmed the xanthomatous nature of the changes in the flat bones (skull and ilium), the long bones being free. The exophthalmos present at the onset of the disorder was found to have been due to a xanthoma of the dura mater. The lymphatic glands throughout the body contained numerous hæmorrhages. The cause of the condition is unknown, although trauma is not infrequent in the history of the onset, as in the case here described. The affection of the flat bones, the onset in a child about two years of age, the skin changes and the exophthalmos, all characteristic of the Schüller-Christian disease, were present in this case; but the curious association with diabetes insipidus, present in some of the published cases, was absent, probably because there were no marked changes in the bones in the region of the sella turcica.

ANOTHER VIEW OF ARTERIO-SCLEROSIS.

ARTERIO-SCLEROSIS has certainly not been neglected by clinicians and experimenters, but it is still an obscure condition. Any thoughtful work on it is therefore welcome, and it is all to the good that Prof. Plesch, in the paper printed elsewhere in this issue, makes suggestions that will not be generally accepted at first sight. It seems to be agreed that arterio-sclerosis, or athero-sclerosis, is a manifestation of a general systemic disease, but the stages leading up to it are not established, and it is on this point that Plesch has definite theories. He advances the view that athero-sclerosis is a healing process in tha it serves no other purpose than to raise the resistance of the walls of already damaged vessels at points o stress or strain, the muscular and elastic elements of the walls of the blood-vessels being previously weakened by an atonic state of the vessel. He sets out to prove his thesis by experimental work, together with clinical and pathological investigations. By a process which he himself has perfected he has injected the coronary arteries, and remarks on the irregularity of their calibre as a result of dilatation; in this connexion it is of interest to note that ophthalmic surgeons rely more on the irregularity of calibre of the retinal vessels as indicating vascular disease than on any other sign found in the fundus. If Plesch's theories are correct he will provide us with an explanation of the failure clinically of drastic lowering of the blood pressure or constant use of vasodilators in the treatment of high blood pressure.

There are many who will disagree with Prof. Plesch when he says that most athletes die before they are 50 years of age, and that they are seldom capable of great physical exertion when they attain middle-life. Possibly this statement needs qualifying, and he is no doubt referring to those who give their whole time to athletics, and not to those who take part in sport merely as a recreation. Much work has been done on the effect of exercise on blood pressure, and it is pretty generally agreed that exercise raises the systolic pressure considerably, and the diastolic to a less extent, thus increasing the pulse pressure; the systolic pressure remains high for a considerable time after the exercise is finished, and slowly returns to normal. This is not considered injurious, and Paul White, in his book on "Heart Disease," says that recent studies indicate that athletes do not suffer early disability or death because of their exercise in youth; even veteran Marathon runners have not shown enough hypertrophy of the heart to be evident on radiographic examination. When such conflicting views are expressed, it seems necessary to have more precise knowledge on this important subject, more especially as athletics are playing an increasingly important part in everyday life.

DRAUGHTS AND COLDS.

King Alfred, so Chesterton informs us, "fought as gravely as a good child at play"; and it is in a similar spirit that C.-E. A. Winslow and Leonard Greenburg have approached the study of Vasomotor Reactions to Localised Drafts.[1] Their inquiry was undertaken "to determine the changes in distribution of the superficial blood-supply resulting from localised drafts, with special view to the possible effects of these changes upon the condition of the upper respiratory tract." There is certainly precedent for this endeavour, and they are able to give an impressive list of workers who have already investigated the truth of the popular belief that one can catch cold by sitting in a draught. Leonard Hill and F. F. Muecke,[2] it appears, using the method of direct observation with a nasal speculum, were the first to report the fact that in a warm atmosphere the mucous membrane of the nose became moist and hyperæmic, and in a cold atmosphere contracted and ischæmic; on sudden chilling, however, the membranes were often found to remain swollen but ischæmic. It is this abnormal condition where the swollen, spongy tissue lacks the protective effect of an ample blood-supply, which is thought to favour bacterial invasion.

Winslow and Greenburg have adopted elaborate methods to decide whether localised draughts play a more definite part than generalised chilling in the ætiology of respiratory infection. Seven different subjects, students of Yale University, submitted to a total of 26 experiments. Low temperatures were secured, in the room used for experiment, by opening the windows and turning off the radiators on the preceding night, and high temperatures by turning on the radiators and closing the windows. The experiments were performed with the windows closed to ensure known conditions within the room. On entering in the morning, the subject stripped himself and lay on a cot for 45 to 60 minutes, after which the following observations were made: the dry and wet-bulb temperature of the atmosphere; the cooling power of the atmosphere by the kata-thermometer; Glatzel mirror observation on the nose of the subject; visual observation of the swelling, redness and moisture of the nose and throat; pulse, respiration, and blood pressure; skin temperature on the surface of the body, and temperature observations on the nose and throat. He was invited to say whether he was comfortable or not. Temperatures were taken at five points in the oral and nasal cavities and at 17 points on the outer skin, and were measured by the thermoelectric method. When these observations were complete a yoke of beaver board partition was used to isolate the subject's head or feet, and the extremity chosen was then exposed to a draught of air from an electric fan for a period of 30 to 50 minutes; the previous observations were then repeated, with the difference that the temperature and kata-thermometer readings were taken both in the vicinity of the body and of the isolated extremity. The draught was then discontinued, and after a period of 5 to 50 minutes the complete series of observations was once more repeated.

The results of the inquiry confirmed those of other workers in showing that chilling of the body surface leads to contraction, ischæmia, and dryness of the mucous membranes of the nose; but there was nothing to indicate that localised, as opposed to general, draughts had any special influence on respiratory infection. Only one of the subjects developed a cold during the experiments. On this occasion, therefore, tradition appears to have been routed. But those who think they can produce immediate rhinorrhœa by walking barefoot on cold floors may still feel a little dissatisfied with the evidence against them.

STEENSEN.

THE Copenhagen Medical Society, taking, we learn, as their model the British habit, have decided to honour prominent men of medicine by instituting commemorative ceremonies, and as a commencement an Oration has been founded in honour of Niels Steensen, more familiar to us as Stensen or Steno, the discoverer of Steno's duct. In Holland as well as in Denmark the great physiologist is known by his Danish name Steensen. The first Steensen Oration was delivered on Jan. 11th by Dr. V. Meisen, well known for his surgical work on varicose veins and hæmorrhoids, an ardent student of medical history, and the translator recently into Danish of Harvey's de Motu Cordis. Steensen's life, as set out by Dr. Meisen, is of great psychological interest. He discovered in 1660 the excretory duct of the parotid, when he was only 22 years old, and was studying in Amsterdam. This was the commencement of an unfortunately short career as a physiologist, but during the next 14 years he showed himself a brilliant investigator; Michael Foster has referred with appreciation to his researches into the physiology of the muscles, of various glands, and of the brain, while Dr. Meisen stated in his address that Steensen was the first to show that the heart was "a muscle and nothing else." He says of the work on the lacrymal glands, that "it explained their structure, working, and functions; maintaining that the ducts were the outlet of the tears, the normal function of which was to keep the surface of the eye and eyelids smooth, and that the passage was only insufficient when the lacrymal fluid was secreted in excessive abundance." In fact Steensen disposed of the accepted belief that the tears emanated directly from by the frequency with which a positive tuberculin reaction is found amongst the general population. Dr. W. R. F. Collis[1] has recently produced strong evidence in support of this view. In a study of eight children suffering with erythema nodosum, five were found to be definitely tuberculous by history, clinical findings, positive Mantoux test, and in three cases by the discovery of tubercle bacilli in the stomach wash-out. The remaining three cases however presented no evidence of tuberculosis and the Mantoux test was negative in all. But these three cases gave a strongly positive reaction to an intradermal injection of hæmolytic streptococcal endotoxin, a reaction which closely resembled the nodes of erythema nodosum itself. These three cases followed acute streptococcal sore-throats in from 5 to 20 days. Dr. Collis's work makes it clear that erythema nodosum is neither a specific disease nor invariably tuberculous in origin, but that the eruption is the result of the action of the soluble products of certain organisms on tissues already hypersensitive. It is thus possible that it may occur in other infections besides those due to the tubercle bacillus and hæmolytic streptococci.

[2] THE LANCET, 1913, i., 1291.

the brain. His work in relation to the functions of the mammæ and the ovaries was equally new and direct, while, before de Graaf, he maintained that the "testes muliebres" were ovaries, and demonstrated the yolk-sac and vitelline duct in a shark. Of his work on the brain, which contained much acute criticism of the knowledge and theories of the day, Dr. Meisen said: "One of his best known contributions to science is his lecture on the anatomy of the brain, delivered in French at Paris in 1664, where he begins in this startling way: 'Gentlemen. Instead of promising You to still your curiosity regarding the anatomy of the brain I have to confess to You my sincere opinion that I do not know anything about it.' . . . He then undertook—as Edward W. Adams[1] says—'the Socratic task of convincing the anatomical world of ignorance.' I quote one passage, which, like many other detached remarks or by-the-way sayings in his writings, has an address even to us in our times: 'To make the necessary inquiries for the discovery of truth a man's whole time must be taken up. . . . Physicians and surgeons cannot comply with this, because of their practise, nor professors because of their public demonstrations. Whole years may sometimes be necessary to discover what may afterwards be demonstrated to others in an hour.' The net effect of Steensen's studies was to correct the views of Willis, who located memory in the cortical substance, imagination in the corpus callosum, and common sense in the striate bodies."

Dr. Meisen proceeded to refer to researches made by Steensen in Italy and Malta into geology, a science to whose pursuit he was led by the dissection of the head of a dog-fish, the teeth of which indicated to him that the glossopetræ of Tuscany were in reality fossil teeth. His treatise "De Solido intra Solidum" is a pioneer work on geologic formation; it is a very rare book, but there are copies in the royal libraries of Copenhagen and in the British Museum, and it was translated into English in 1671. While engaged on this work in Italy he was summoned back to Copenhagen to take up the professorship of anatomy, but he held that office for only two years, for already theological leanings acquired during his Italian sojourn had become predominant. Accordingly, at the age of 36 he returned to Italy, and under the patronage of the Grand Duke of Tuscany, at whose court he lived, his scientific works were published, while the author went over to the Catholic faith, became absorbed in the teachings of the Church, and was eventually appointed to an episcopy in North Germany. He died in 1686, his death, Dr. Meisen suggests, being hastened by the rigorous manner of life which he imposed on himself out of piety, and is buried in Florence, a bust being placed over his tomb in the Basilica San Lorenzo in 1883.

Dr. Meisen closed his Oration by pointing out that in Steensen's time the classic authors and the Old Testament constituted the scientific basis of investigation, most of the scientific discoveries being made by men who were first of all scholars, as was Harvey. Steensen in particular was an ardent student of mathematics, the mathematical sense and the vigorous imagination being remarkably blended in him, as they were in Pasteur whom he resembles both in powers of intuition and boldness of conclusions. Comparing Steensen's work with that of his friend, and comrade, Malpighi, Dr. Meisen says: "It must always be remembered that Malpighi possessed that quite new instrument the microscope which enabled him to find gold where others could not, while he had a working life of 30 years and Steensen one of only 14 years." Certainly the orator justified the description of the Danish savant given by Michael Foster—"a singular man who 300 years ago pierced into questions which are still moving us at the present day."

---

[1] Adams in Medical Library and Historical Journal, 1904, vol. II., No. 1.

A MORE SENSITIVE WASSERMANN TEST.

At an early stage of its career the Medical Research Council appreciated that everything should be done to bring about the adoption of a thoroughly reliabl Wassermann test. A series of observations (Specia Reports Series Nos. 14, 21, and 78) were carried out by workers in this country, the result of which wa to show that a properly standardised Wasserman test possessed a very high degree of specificit Recently the introduction of certain precipitin tests in particular the Kahn test in America, suggested i certain circles that the Wassermann test was no all that it should be, both in regard to sensitivit and to specificity. But at the recent Laborator Conference on the sero-diagnosis of syphilis, held a Copenhagen in 1928 under the health organisatio of the League of Nations, it was shown that th Wassermann test as carried out in this country ha nothing to fear in comparison with any of the flocc lation tests, and that the Wassermann test had high, if not higher, qualities of specificity than an test yet devised for syphilis. It had, however, bee felt that in the ordinary standardised Wasserman test, as used in this country, a few cases might ha been missed; in other words, that the test might more sensitive if that could be arranged witho losing any of its high specificity. Several attemp have been made to increase the sensitivity of t Wassermann test by such things as fixation in t cold, decrease in the amount of complement, a changes in the antigen proportion, without apparent any very great success. It is therefore very intere ing to see that Dr. Wyler has pursued this matt further[1] and, as an outcome of his investigatio has devised a method which he considers has increas the sensitivity of the Wassermann test by somethi like 20 per cent. The procedure he adopts is sim to double the quantity of the patient's serum in t test as ordinarily used. This, as he says, is of cou no new principle; it is, for instance, used in carryi out the reaction with cerebral spinal fluid. Perha this is an admission on Dr. Wyler's part that satisfactory quantitative Wassermann test can carried out by using varying quantities of patien serum. Using increased amounts of sera, Dr. Wy has done a series of tests on 1000 sera, over 400 which were from known cases of syphilis. Compa tive tests were carried out against the ordina Wassermann and against the Sigma test, and it see that the test with the newer technique is definite more sensitive than either. Confirmation of the findings will greatly enhance the reliance which placed in this country on the Wassermann te Dr. Wyler is to be congratulated on the lucidity wi which he has put forward his data.

---

[1] A Method of Increasing the Sensitiveness of the Wasserma Test. By E. J. Wyler, M.C., M.D. Lond.; Ministry of Heal Reports on *Public Health and Medical Subjects*, No. 67. H. Stationery Office. 1932. Pp. 15. *1d.*

MANCHESTER VICTORIA MEMORIAL JEWISH HOSPITAL.—It has been decided that in future the visiting hours shall be in the evening, on the ground of convenience for the working-classes.

SPECIAL ARTICLES

THE LANCET COMMISSION ON NURSING.

THE Final Report of THE LANCET Commission on Nursing was issued to-day.[1] It will be remembered hat the Commission was appointed in December, 930, to inquire into the reasons for the shortage of andidates, trained and untrained, for nursing the ick in general and special hospitals throughout the country, and to offer suggestions for making the ervice more attractive to women suitable for this necessary work. The members of the Commission were:—

The Earl of CRAWFORD and BALCARRES. P.C., K.T., F.R.S. (Chairman).

Miss M. D. BROCK. O.B.E., M.A., Litt.D., Headmistress, the Mary Datchelor Girls' School.

Miss L. CLARK, M.B.E., R.R.C., Matron, Whipps Cross Hospital.

Prof. HENRY CLAY, M.A., D.Sc., late Professor of Social Economics in the University of Manchester.

Miss R. E. DARBYSHIRE, R.R.C., Matron, University College Hospital.

Prof. F. R. FRASER, M.D., F.R.C.P., Professor of Medicine in the University of London, Physician to St. Bartholomew's Hospital.

Mr. A. LISTER HARRISON, J.P., Chairman. Committee of Management, Metropolitan Hospital.

Dr. ROBERT HUTCHISON, F.R.C.P., Physician to the London Hospital and to the Hospital for Sick Children, Great Ormond-street.

Mrs. OLIVER STRACHEY, Chairman, Employment Committee, London and National Society for Women's Service.

Miss EDITH THOMPSON, C.B.E., Member of Council, Bedford College, University of London.

Sir SQUIRE SPRIGGE, M.D., F.R.C.P., Editor of THE LANCET, with

Dr. M. H. KETTLE, an assistant editor, as honorary secretary.

The Commission held 24 meetings, and the various subcommittees appointed held 25 meetings in addition.

At the first meeting of the Commission, held on Dec. 8th, 1930. it was decided to issue a questionnaire addressed to the responsible authorities of all the hospitals approved as training schools by the General Nursing Councils, and also to a sample of the hospitals not so approved. The procedure adopted in connexion with the issue of this questionnaire, and with the analysis of the information received. was set out in the First Interim Report of the Commission, which was published in THE LANCET of Feb. 28th, 1931. The Second Interim Report, containing the statistical analysis by Dr. Bradford Hill of answers to the questionnaire, was published in THE LANCET of August 15th. 1931. Both Interim Reports are reprinted as appendices to the Final Report. The information analysed was collected from 686 hospitals and relates to the conditions of service of a nursing staff numbering nearly 44,000.

Two other questionnaires were subsequently sent out respectively to trained nurses working in hospitals and to probationers known to have a good secondary education. In addition, groups of girls still at school and older girls were questioned. The results of all these inquiries are summarised in the Final Report.

A gratifying response was moreover received to a request for evidence, to which the press of the country gave generous publicity. The mass of correspondence received by the Commission was in itself an indication of the wide interest aroused in the investigation. We set out below the Table of Contents of the Final Report and the Introduction. Other excerpts from the Report will appear next week.

Table of Contents.

I.—PREFACE.—INTRODUCTION.

Adaptation rather than Reconstruction—Dependence of the Hospitals on Student Labour—Effect of Shortage of Nurses on the Patient—Safeguards against Over-recruitment of Nurses.

II.—EVOLUTION OF BRITISH NURSING.

Mediæval Developments—The General Decline in Nursing—The Decline of Nursing in this Country—The Plight of Certain London Hospitals—Early Efforts at Reform—The British Nursing Orders—Florence Nightingale—Modern Times.

III.—THE PRESENT POSITION.

The Barrier to Coöperation—Misconceptions on Both Sides—"What More do They Want?"—The Value Placed on Routine—A Conflict of Ideals—Criticism from Within—Responsibility without Trust—The Traditional Outlook and the Modern Outlook.

IV.—SHORTAGE OF CANDIDATES FOR THE NURSING PROFESSION.

(A) *Extent of Shortage.*

(B) *Kind of Shortage.*
Wastage—Suitability a Relative Term—Unpopularity of Nursing among Secondary School Girls.

(C) *Reasons for Shortage.*
The Age of Entry—Hours On and Off Duty—Ward Work and Study—Physical Strain—Social Life and Restrictions—Uniform, Food, and Accommodation—Pay and Superannuation—Professional Status—The Adjustments Required.

V.—DISCUSSION OF MAIN REASONS FOR SHORTAGE AND RECOMMENDATIONS.

(A) *The Gap between School and Hospital.*
Classification of the Possible Recruits—Schemes to Provide Continued General Education—Schemes to Provide Special Education: (*a*) Pre-nursing Courses (Preparatory); (*b*) Pre-nursing Courses to Give Exemption from the Preliminary State Examination—Schemes to Provide Remunerative Occupation between 16 and 19—Discussion—Recommendations.

(B) *Pay and Prospects.*
(*a*) Cost of Training: Who Pays for the Nurse's Training?—What the Hospital Saves by Employing Student Labour—Payment of Fees for Training—Need for Flexibility and Experiment—A Compromise—Endowment and Subsidy of Schools of Nursing—Summary—Recommendations. (*b*) Anticipated Earnings: Service in Hospitals—Recommendations—Relation of Cost of Nursing to Hospital Expenditure—Pay and Prospects in Special Public Services—District Nursing—Recommendation—The Public Health Service—Private Nursing. (*c*) Prospects of Employment. (*d*) Provision for Old Age: Superannuation Schemes—Obstacles to Free Migration—Constructive Proposals—Recommendations.

(C) *Hours of Work.*
General Considerations—Reasons for Adjustment—Methods of Reckoning Hours of Work—Plans for Adjustment—The Three-Shift Plan—Modification of Hours under the Two-Shift Plan—Recommendations.

(D) *Conditions of Admission and Service.*
Sources of Discontent—Position of the Matron. (*a*) Conditions of Admission: The Initial Reception—Contrasts in Rules and Contract Forms—Suspension and Dismissal—Recommendations. (*b*) Conditions of Institutional Life: Accommodation—Diet—Social Relations in the Nurses Home—Bedtime—Supervision of Bedrooms—Smoking—Uniform—Recommendations. (*c*) Facilities for Social Life Outside the Institution: Advance Notice of Off-duty Time—Removal of Restrictions in the Evening—Telephone—Guest Rooms—Compulsory Attendance at Meals—Annual Holiday—Recommendations.

(E) *Professional Education.*
(*a*) Training for the Preliminary State Examination: Present Conditions—Recommendations. (*b*) Training for the Final State Examination: Task of the Sister Tutor—Possible Modifications of the Examination—Examination Centres—Rest before Examinations—Recommendations. (*c*) Recognition of Previous Training: Some Obstacles Considered—The Advantages of Interchangeability—Recommendation. (*d*) Domestic Work—Recommendation.

the brain. His work in relation to the functions of the mammæ and the ovaries was equally new and direct, while, before de Graaf, he maintained that the "testes muliebres" were ovaries, and demonstrated the yolk-sac and vitelline duct in a shark. Of his work on the brain, which contained much acute criticism of the knowledge and theories of the day, Dr. Meisen said: "One of his best known contributions to science is his lecture on the anatomy of the brain, delivered in French at Paris in 1664, where he begins in this startling way: 'Gentlemen. Instead of promising You to still your curiosity regarding the anatomy of the brain I have to confess to You my sincere opinion that I do not know anything about it.' . . . He then undertook—as Edward W. Adams[1] says—'the Socratic task of convincing the anatomical world of ignorance.' I quote one passage, which, like many other detached remarks or by-the-way sayings in his writings, has an address even to us in our times: 'To make the necessary inquiries for the discovery of truth a man's whole time must be taken up. . . . Physicians and surgeons cannot comply with this, because of their practise, nor professors because of their public demonstrations. Whole years may sometimes be necessary to discover what may afterwards be demonstrated to others in an hour.' The net effect of Steensen's studies was to correct the views of Willis, who located memory in the cortical substance, imagination in the corpus callosum, and common sense in the striate bodies."

Dr. Meisen proceeded to refer to researches made by Steensen in Italy and Malta into geology, a science to whose pursuit he was led by the dissection of the head of a dog-fish, the teeth of which indicated to him that the glossopetræ of Tuscany were in reality fossil teeth. His treatise "De Solido intra Solidum" is a pioneer work on geologic formation; it is a very rare book, but there are copies in the royal libraries of Copenhagen and in the British Museum, and it was translated into English in 1671. While engaged on this work in Italy he was summoned back to Copenhagen to take up the professorship of anatomy, but he held that office for only two years, for already theological leanings acquired during his Italian sojourn had become predominant. Accordingly, at the age of 36 he returned to Italy, and under the patronage of the Grand Duke of Tuscany, at whose court he lived, his scientific works were published, while the author went over to the Catholic faith, became absorbed in the teachings of the Church, and was eventually appointed to an episcopy in North Germany. He died in 1686, his death, Dr. Meisen suggests, being hastened by the rigorous manner of life which he imposed on himself out of piety, and is buried in Florence, a bust being placed over his tomb in the Basilica San Lorenzo in 1883.

Dr. Meisen closed his Oration by pointing out that in Steensen's time the classic authors and the Old Testament constituted the scientific basis of investigation, most of the scientific discoveries being made by men who were first of all scholars, as was Harvey. Steensen in particular was an ardent student of mathematics, the mathematical sense and the vigorous imagination being remarkably blended in him, as they were in Pasteur whom he resembles both in powers of intuition and boldness of conclusions. Comparing Steensen's work with that of his friend, and comrade, Malpighi, Dr. Meisen says: "It must always be remembered that Malpighi possessed that quite new instrument the microscope which enabled him to find gold where others could not, while he had a working life of 30 years and Steensen one of only 14 years." Certainly the orator justified the description of the Danish savant given by Michae Foster—"a singular man who 300 years ago pierced into questions which are still moving us at the presen day."

A MORE SENSITIVE WASSERMANN TEST.

At an early stage of its career the Medical Researc Council appreciated that everything should be don to bring about the adoption of a thoroughly reliabl Wassermann test. A series of observations (Speci Reports Series Nos. 14, 21, and 78) were carried ou by workers in this country, the result of which wa to show that a properly standardised Wasserman test possessed a very high degree of specificit Recently the introduction of certain precipitin test in particular the Kahn test in America, suggested certain circles that the Wassermann test was n all that it should be, both in regard to sensitivi and to specificity. But at the recent Laborato Conference on the sero-diagnosis of syphilis, held Copenhagen in 1928 under the health organisati of the League of Nations, it was shown that t Wassermann test as carried out in this country h nothing to fear in comparison with any of the flocc lation tests, and that the Wassermann test had high, if not higher, qualities of specificity than a test yet devised for syphilis. It had, however, be felt that in the ordinary standardised Wasserma test, as used in this country, a few cases might ha been missed; in other words, that the test might more sensitive if that could be arranged witho losing any of its high specificity. Several attem have been made to increase the sensitivity of Wassermann test by such things as fixation in cold, decrease in the amount of complement, changes in the antigen proportion, without apparen any very great success. It is therefore very intere ing to see that Dr. Wyler has pursued this mat further[1] and, as an outcome of his investigatio has devised a method which he considers has increa the sensitivity of the Wassermann test by someth like 20 per cent. The procedure he adopts is sim to double the quantity of the patient's serum in test as ordinarily used. This, as he says, is of con no new principle; it is, for instance, used in carry out the reaction with cerebral spinal fluid. Perh this is an admission on Dr. Wyler's part tha satisfactory quantitative Wassermann test can carried out by using varying quantities of patie serum. Using increased amounts of sera, Dr. Wy has done a series of tests on 1000 sera, over 400 which were from known cases of syphilis. Compa tive tests were carried out against the ordin Wassermann and against the Sigma test, and it see that the test with the newer technique is definit more sensitive than either. Confirmation of th findings will greatly enhance the reliance which placed in this country on the Wassermann t Dr. Wyler is to be congratulated on the lucidity w which he has put forward his data.

MANCHESTER VICTORIA MEMORIAL JEWISH H PITAL.—It has been decided that in future the visiting ho shall be in the evening, on the ground of convenience for working-classes.

[1] A Method of Increasing the Sensitiveness of the Wasserm Test. By E. J. Wyler, M.C., M.D. Lond.; Ministry of Hea Reports on Public Health and Medical Subjects, No. 67. H Stationery Office. 1932. Pp. 15. *1d.*

has to wait for attention, or is so conscious of the overwork of the nurses that he hesitates to ask for it; when the doctor's orders are carried out with less promptness and skill than they should be; and when anxiety to get the necessary work done obsesses the minds of the senior nurses to such an extent as to lead them to spur their juniors to get through their tasks quickly, while giving little teaching in the individual care of patients. In hospitals where acute shortage exists, new probationers may be flung into understaffed wards to take their part in the daily struggle against time. The wards have to be kept clean and tidy, and so many patients have to be washed and fed and settled, dressed or dosed, that the probationers are bewildered and discouraged; the patient feels that he gets little personal attention; and the trained staff complete the essential routine work only by sacrificing their own scanty leisure. It will hardly be possible to protect hospital patients from suffering from such a shortage unless it is remedied soon. It is an axiom in the nursing profession that the patient comes first, and throughout our work it has been the patient whose interests have been uppermost in our minds. It is useless to provide hospitals and doctors for the sick unless an adequate nursing service can be assured.

SAFEGUARDS AGAINST OVER-RECRUITMENT OF NURSES.

5. It would not, however, be justifiable to invite more probationers to take a nurse's training than the profession could absorb, merely in order to provide our hospitals with student labour. The number of apprentices must be kept within reasonable bounds, or eventually unemployment will result. The limitation by the General Nursing Councils of the hospitals approved as training centres to those which can provide adequate experience should prove a safeguard against this danger. As the value of training leading to State registration, as opposed to that leading only to a hospital certificate, becomes more generally understood by the public, non-approved hospitals will no longer enlist the services of students; these hospitals will then provide additional posts for nurses trained at the approved training schools. In this way the nursing profession will be safeguarded from overcrowding when the removal of misconceptions and prejudice, and the adjustment of conditions of training and service in the approved hospitals make it again a popular avenue of employment.

(*To be continued.*)

MEDICINE AND THE LAW.

Substantial Sentence on Bogus Doctor.

George Edward Williams, whose real name was given as Flaxman, pleaded guilty at the Central Criminal Court on Feb. 8th to charges which were outlined in THE LANCET of Jan. 23rd at p. 203. The accused had apparently had the courage to annex to himself the name and degrees of an existing medical practitioner resident in Wales. His medical experience, according to his counsel, consisted of his having been a steward in a hospital and of service in the ranks of the R.A.M.C. during the war. The gravest charge against him was that of having committed perjury on the trial of an action in the Clerkenwell county court where, posing as an expert medical witness, he had sworn that he had been in practice for 26 years, and that he possessed the qualifications M.D. (Cambridge), M.R.C.S., L.R.C.P., and D.P.H. A second charge concerned his unlawful possession of drugs within the Dangerous Drugs Acts; not being a registered medical practitioner, he had no authority under the Acts and Regulations to possess or supply such drugs. On each of these two charges he was sentenced to three years' penal servitude, sentences to run concurrently. On a third charge—making an untrue statement for the purpose of procuring a passport—no sentence was passed.

The case neatly illustrates facts of which the medical profession is aware and the general public is largely ignorant. The fine old preamble of an Act of Henry VIII. states that "the science and cunning of physic and surgery (to the perfect knowledge whereof be requisite both great learning and ripe experience) is daily within this Realm exercised by a great multitude of ignorant persons of whom the greater part have no manner of insight into the same . . . to the high displeasure of God, great infamy to the faculty, and the grievous hurt, damage, and destruction of many of the King's liege people, most especially of them that cannot discern between the cunning and the uncunning"—words which served as a type for the preamble to the Medical Act of 1858 which in simpler language recites that it is "expedient that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners." The modern Statute is not concerned with the divine displeasure or with the great infamy to the faculty; but it does take note of the peril to the life and health of a patient where an untrained and unqualified man like Flaxman imposes upon the confidence of the sick and suffering. From the public point of view the true gravamen of the accusations against Flaxman is this fraudulent and dangerous posing as the possessor of expert qualifications. The law allows great latitude. Flaxman, though unregistered and unqualified, could, with a remarkable degree of impunity, administer almost any kind of medical treatment, and (as recent unsuccessful proceedings in R. *v.* Ensor indicated) call himself 'doctor' or allow himself to be so called. The one thing which the law forbids is his falsely representing himself to be a registered practitioner or to have certain medical qualifications. This offence Flaxman undoubtedly committed. Was he charged with it? No. Why not? Because the punishment is negligible. The following statutory table of maximum penalties for the offence of falsely representing oneself to be registered or duly qualified in various professions is instructive:—

Medical practitioner ..	£20 (21 & 22 Vict., c. 90, s. 40).
Veterinary surgeon ..	£20 (44 & 45 Vict., c. 62, s. 17).
Architect	£50 for first offence, £100 for any subsequent offence (21 & 22 Geo. 5, c. 33, s. 10).
Dentist	£100 (11 & 12 Geo. 5, c 21, s. 1).

It is more than twice as serious, therefore, to pretend to be a registered architect, and five times as serious to pretend to be a dentist, as it is to pretend to be a registered medical practitioner. The gross fraud of which Flaxman was guilty led him into certain consequential or subsidiary actions. Having once adopted the pose of being a duly-qualified practitioner, he was committed to consequences such as maintaining his pose in the witness-box or prescribing dangerous drugs. For these consequential actions he receives the substantial sentence of three years' penal servitude. For the cardinal and principal fraud, the source from which those actions flowed, the penalty is so trivial as not to be worth inflicting.

Stealing a Practitioner's Name.

Flaxman's case is the second instance within the past few months of an unqualified person assuming

The Introduction to the Report.

In the introduction the scope of the Report and certain important considerations are defined as follows:—

1. Conditions of service and education in the nursing profession are being closely studied in many countries and from many points of view. Our own contribution to this study is a report on the shortage of candidates for work in hospitals in this country, and on means by which this shortage may be overcome. The object of our recommendations has been to suggest an adjustment of the conditions offered, in order to attract in sufficient numbers young women of the right type to fulfil an essential public service. We have not sought to look far ahead, and where we have considered such subjects as the costing system of hospitals, the arrangement and standards of professional examinations, the amenities of a nurse's life, or the permanent prospects open to her, our terms of reference have been borne constantly in mind.

ADAPTATION RATHER THAN RECONSTRUCTION.

2. We have confined our attention as far as possible to proposals which would involve adaptation rather than fundamental change in the system on which the nursing services of this country are at present carried on. For this reason we have not dealt except in outline at the end of the Report (see paras. 338 to 346) with certain issues affecting the internal organisation of the nursing profession. These include the establishment of schools of nursing in connexion with universities; the replacement of the present five registers by one register with supplementary diplomas; a *substantial* shortening of courses of training; and the official recognition of two grades of nurses. It would be difficult to predict the ultimate effect on recruitment for work in hospitals of any of these changes. In any case, a reconsideration of the whole basis of State registration only 12 years after its inception would be premature, at least until a real effort has been made to remove the causes which make work in hospitals no longer attractive to young women. Progress can, in our opinion, best be made by accepting the complicated system which was set up as a compromise between many interests, while recognising that the lack of eagerness on the part of girls from *secondary schools to train* as nurses shows that adjustments are needed unless the whole system i to break down. We have dealt chiefly with the adjustments required in the hospitals of the country taken as a whole, believing that the peculiar difficultie of certain types of hospitals will be met more easil when those common to nearly all hospitals have bee recognised and, as far as possible, resolved. For thi reason we have not devoted separate Sections t each of the groups of hospitals differentiated in D Bradford Hill's analysis (Appendix xviii.). Most our recommendations apply, in greater or less degre to Children's hospitals, Fever hospitals, and Affiliate *Associated*, and Reciprocal hospitals. This is al true of Tuberculosis and Mental hospitals, thoug these have been considered separately.

THE DEPENDENCE OF THE HOSPITALS ON STUDENT LABOUR.

3. To restore the popularity of nursing amon educated girls has been the chief objective of o inquiries. The economic and the administrati difficulties of hospitals, the vocational ideals of sor nurses and the professional aspirations of othe concern us only in so far as they promote or hind our object of inducing enough educated girls to cor forward to dispel anxiety about the nursing care the sick in hospitals. We have had to devote clo attention to conditions of training as well as employment, because hospitals have long depend for their nursing service largely on students eag *to learn. The ratio of* the untrained to the train staff is approximately 2 to 1 even if staff nurses a all counted as trained staff; thus, the fact th admission to a course in nursing is no longer keen sought means *not* only the prospect of a shortage nurses in the future, but an actual shortage of worke in hospitals to-day.

THE EFFECT OF SHORTAGE OF NURSES ON THE PATIENT.

4. Hitherto the patients have rarely been allow to suffer. Deficiency in the quantity and quali of the candidates for nursing them has been met imposing an increased strain on the members the trained staff and on those who do come forwa for training. But the time must come, and it h already come in some hospitals, when the patie

preliminary sciences and to the special branches. A very large amount of the work of the general practitioner is concerned with disorder of function unaccompanied by obvious disorder of structure. The present curriculum is much too largely concerned with the latter. Much more time must be made available to the student for his study of practical medicine. The strain on the mental and physical condition of the student towards the end of his third academic year is absurd: but a very small part of that strain is, however, directed to clinical work. A judiciously reorganised curriculum would allow attention to be paid to some vitally important subjects which at present receive very inadequate attention—e.g., nutrition, heredity, psychotherapy, physicotherapy, antenatal work, and preventive medicine.

Dr. Watson outlined a scheme of revision for the medical curriculum of the University of Edinburgh.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

CIVIL AND MILITARY MEDICAL COÖPERATION.

PARTLY as a result of the constitution of the Indian Medical Service, the army medical organisation in India, ever since the British connexion, has been intimately associated with civil work. Up to quite recent times it was the Indian Medical Service, almost exclusively, which ran not only the important hospitals, but also the medical colleges and schools, and a large proportion of the cadre was employed in this way. At the same time it was always understood that the army had the first claim, and at times of great military stress the bulk of that portion of the service which was employed in civil work reverted to the army. But conditions have changed in the course of Indianisation. Civil appointments have been curtailed, and the connexion between the civil and military branches is not so close as it used to be. Further, from time to time it has been urged by nationalist interests that civil medicine should be entirely divorced from military, and attacks are still made on the Indian Medical Service with this object in view. It is therefore interesting to note that, as a result of the present financial stringency, which has hit the recently extended Bombay hospitals particularly hard, influential Indians are now proposing that the army medical department should come to the rescue. Figures are quoted to show that, in times of peace, the military medical establishments are far in excess of requirements, and it is suggested that some part of them should be employed in the civil hospitals. As so often happens in cases of this kind, all the old arguments which tend to the opposite conclusion are forgotten, and when it is said that in 1931 the army had 12,743 beds at its disposal, and a personnel of 16,648 to look after them, the exponents of the new proposals seem to assume that nothing further remains to be discussed. The fact is of course that such figures include not only hospital attendants, but ambulance corps, and various other details who have nothing to do with actual hospital work; while the necessity of being prepared for military emergencies is entirely ignored. Many good authorities have thought that a close connexion between the military and civil hospitals and medical services serves the needs of India better than the entire divorce which has recently been advocated by both medical and lay nationalist enthusiasts. This association is still maintained, to some degree, through the medium of the Indian Medical Service, but with the contraction which has taken place within recent years it has greatly diminished, and to reverse the policy which has been persistently pursued on account of a temporary crisis hardly seems reasonable.

THE SOCIAL EVIL.

International collaboration with a view to checking the traffic in women and children was started about 30 years ago. The war against this traffic is now being extended to the east, under the auspices of the League of Nations, and various countries which are concerned, including India, have expressed their willingness to coöperate in preliminary inquiries. A committee consisting of three members, one American, one Swedish, and another a Pole, started work in October last. It is expected that about 18 months will be spent in visiting various eastern countries. This will no doubt strengthen the efforts already being made in some large Indian cities to deal with prostitution. In Bombay a Bill was passed last year to enable the police to close brothels. Owing to the civil disobedience movement, which threw a great strain on the authorities, action was delayed for some time, but an energetic campaign is now in operation. Measures were first taken to close the foreign houses. All were visited by the police, and the proprietors warned that unless they broke up their establishments by a certain date they would find themselves in jail. It is intended to carry out the same procedure with regard to Indian brothels later on. How far these measures will be successful remains to be seen. The police authorities at one time certainly doubted whether any legislation of the kind would do more than drive the evil underground. One good result, at all events, should be some safeguarding of British and foreign seamen in the port, and from the medical point of view anything which holds out a prospect of limiting the incidence of venereal diseases, which are so rampant throughout the East, is worthy of support.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

HUNTERIAN FESTIVAL.

AFTER the delivery of the Hunterian Oration (see p. 381) on Feb. 15th the President and Council held the Hunterian festival dinner in the library of the College. The company included:—

Members of Council.—Mr. R. P. Rowlands and Mr. Sampson Handley (Vice-Presidents), Sir Holburt Waring, Prof. E. W. Hey Groves, Sir Percy Sargent, Prof. G. E. Gask, Mr. McAdam Eccles, Sir Charles Gordon-Watson, Prof. A. H. Burgess, Mr. Warren Low, Mr. Victor Bonney, Prof. G. Grey Turner, Mr. Hugh Lett, Prof. Leonard Gamgee, Prof. R. E. Kelly, Prof. Graham Simpson, and Mr. A. J. Walton: with Sir Arthur Keith (Conservator of the Museum) and Mr. Forrest Cowell (Secretary).

Guests.—Sir Henry Betterton (Minister of Labour), Lord Atkin, the Dean of St. Paul's, Sir Gowland Hopkins, P.R.S., Dr. T. Watts Eden (President of the Royal Society of Medicine), Sir George Makins, Sir Farquhar Buzzard, Sir D'Arcy Power, Surgeon Vice-Admiral R. St. G. S. Bond, Sir Harold Fawcus, Sir William Bragg, F.R.S., Mr. Charles Lupton, Mr. C. Tate Regan, F.R.S., Prof. William Bulloch, F.R.S., Mr. R. H. Burne, F.R.S., Sir Frank Colyer, Sir Henry Dale, F.R.S., and Sir David Murray, R.A.

Lord MOYNIHAN, proposing the health of The Guests, said that the College was famous for its hospitality: its visceral aristocracy included parts of the two oldest inhabitants of Europe, the Piltdown and Gibraltar skulls; the most ancient mummy in existence; the heart of the Pharoah of the Oppression;

the name of a practitioner whose name is on the Register. His case has been discussed in the preceding paragraph from the public point of view. A practitioner whose name is thus borrowed and abused has a personal grievance. Adventurers must somehow be discouraged and prevented from dipping at random into the pages of the Medical Register and annexing any name they fancy. Apart from other legal aspects, such conduct possibly discloses an offence against the Registration of Business Names Act, 1916. "Business" in that statute includes "profession," and "every individual having a place of business in the United Kingdom and carrying on business under a business name which does not consist of his true surname . . . shall be registered in the manner directed by this Act." The penalty for default in registration runs at the rate of £5 a day. The statute was a war-time enactment. It hardly seems an appropriate weapon against frauds such as Flaxman's, and there may be awkwardness in applying it. It creates, however, no difficulties for the honest practitioner or for bona-fide changes of name.

Hospital Death Due to Mistake in Medicine.

An unfortunate mistake in a local hospital led to the holding of an inquest at Dartford on Feb. 8th. Evidence was given that death was due to heart failure brought about by belladonna poisoning. It appeared that a probationer nurse, aged 17, had been given the key of the medicine chest for the purpose of administering aperients to patients. Unhappily a bottle containing a mixture of belladonna and glycerin was taken from the medicine chest instead of a bottle containing syrup of figs. It was stated that the medicine chest stood low down and was badly lighted. It should have been cleared out each week, but this had not been done for some time. It was the usual practice to keep the special drugs on one side of the chest, but there was no partition. Some bottles containing poison were blue; others had nothing to distinguish them. Neither the matron nor the sister in charge could explain how or when the belladonna bottle found its way into the medicine chest. The coroner observed that the evidence showed great want of care and supervision. The young nurse was hardly old enough to have charge of the administration of medicines, but the blame should not be laid on her shoulders alone. The bottles and labels should not have been used as they were, and the shape and size of the bottles should not have been similar. A verdict of "accidental death" was returned.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

EDINBURGH MUNICIPAL HOSPITALS AND THE TEACHING OF MEDICINE.

THE Edinburgh hospital scheme is moving forward. It is probable that the report of the joint committee representing the University and the Corporation will be approved of, and that an agreement will be entered into with the University on the lines of that report. The proviso is made that the agreement may be terminated or revised at the end of three years, and also that the sum to be paid to the University on account of services rendered by the part-time staff in respect of municipal hospitals shall not exceed £2000 per annum. A draft scheme is to be prepared and submitted to the Department of Health for Scotland for the reorganisation of the hospitals belonging to the Edinburgh corporation at Pilton, Craigleith, and Seafield, and this draft scheme will contain provisions for removing Craigleith and Seafield hospitals from the category of poor-law hospitals in so far as Edinburgh residents are concerned.

This important decision means that Craigleith and Seafield hospitals will now be converted into general hospitals under the health committee, and will be available for teaching. Pilton hospital is already in this position. The arrangement with the University is both for teaching and for treatment. To protect the Royal Infirmary and the other voluntary hospitals, as regards the part-time staff, the appointments should be made by the University and the corporation jointly.

The three institutions will be taken as constituting one hospital system. According to the town clerk's statement, four main units would be formed: (1) medical; (2) surgical; (3) obstetrical and gynæcological; (4) children. The staff of each unit would consist of a director, who would have the status of a full physician or surgeon; one assistant physician or surgeon, or more; and one clinical tutor or more. There would be the part-time officers under the joint appointment, and, in addition, full-time resident physicians and surgeons. The general administration of this hospital system would be under the control of the medical officer of health. The corporation will thus have at their command the best medical service which the city can produce, in the same way as the Royal Infirmary. The joint report by the University and the corporation recognises the advantages of this arrangement. Teaching ensures greater regularity and thoroughness of working. The provision of a staff composed of teachers increases confidence. The medical school benefits by the increased number of beds. The students will have the advantage of more clinical instruction in chronic illness. Clinical research will find abundant material of a kind not provided by the voluntary hospitals. The training of nurses will benefit by the better facilities. The pressure on the voluntary hospitals will be relieved.

As regards the new facilities for teaching and research, it is accepted that the students of the school of medicine of the Royal Colleges shall share the opportunities with those of the University. Thus the difficulty between the University and the extra-mural school has been solved.

THE REFORM OF MEDICAL EDUCATION.

Addressing the Edinburgh Medico-Sociological Club on Feb. 5th, Dr. Chalmers Watson pointed out that not a few prominent critics of modern education have condemned the prevailing tendency towards excessive specialisation in teaching, resulting in a failure to teach the essential fundamental principles. It is increasingly recognised, he said, that there is something inherently wrong with our present system of medical education. Students are systematically overtaught and overcrammed; they have no time to teach themselves, their training in clinical medicine is seriously inadequate. The curriculum is framed without adequate orientation to the later work of the practitioner. This defect is not due to lack of teachers. In the last 40 years the number of medical graduates in Edinburgh has lessened to the extent of 60 graduates, whereas the number of teachers has increased by 68, this taking no account of the increase in the clinical teaching staff.

In former days, said Dr. Watson, medicine and clinical medicine rightly constituted the "hub" of the medical curriculum; to-day it is hardly too much to say that they are subordinated to the circumstances of the case, having in mind particularly the number of persons on the respondent's panel who appear to have required the administration of hypodermic injections of morphine," the Inquiry Committee reports that it is satisfied that the insurance committee's allegation on this point is made out—namely, that the Dangerous Drugs Acts disability placed the respondent in a position in which he could not comply with his Terms of Service.

The decisions of the Minister of Health in these cases of complaint against a panel practitioner are necessarily based upon the particular facts of each investigation rather than upon any general principle evolved by a series of recorded judgments. The cases naturally fall into groups according to the degree of culpability and the standardised penalties deemed appropriate. One case does not otherwise serve as a precedent for another, but the result in the Liverpool case gives a warning of what may be expected where similar facts are proved.

Anæsthetics in Panel Practice.

When the scheme for panel practice was drawn up, the ideal arrangement suggested and embodied in the Terms of Service was that a doctor should be able to call in a fellow practitioner to give an anæsthetic when wanted for an operation, payment to come out of the local fund as a first charge on the medical funds for all services. It was generally agreed between panel and insurance committees, and included in the local distribution scheme, that appropriate fees would be one guinea for a general anæsthetic and half a guinea for gas. No fee is paid for a local anæsthetic. The claim for the anæsthetic fee has to reach the insurance committee within seven days of the administration, giving particulars of the case, including the time taken for the operation, the anæsthetic used, and so forth. The insurance committee in turn sends the form to the panel committee for review. The practice of panel committees varies throughout the country; some refuse all anæsthetic payments on the assumption that such service is reciprocal. Others allow certain claims, but not where partners or assistants have acted as anæsthetist. The matter has been considered by the London Panel Committee on several occasions in the past year. In London where it has been the custom of the committee, except in very exceptional cases, to pass all claims, their number has increased largely, although many practitioners give anæsthetics for each other without making any claim. Investigation showed that over 50 per cent. of claims were made by partners or by principal and assistant, and further examination suggested that a number of the cases might have been operated upon with a local anæsthetic without fee. For this and even more cogent reasons, the committee passed a resolution that they wished anæsthetics to be included in the general services without special payment. As this involved altering the Terms of Service for the whole country, a second resolution was passed asking the London Insurance Committee to agree to the alteration of the local distribution scheme whereby all anæsthetics should be paid for at a nominal fee of one shilling until such time as the Ministry of Health agreed to incorporate anæsthetics in the general services obligatory on all panel doctors. It will be interesting to see the effect of this alteration if sanctioned by the Ministry.

Excessive Prescribing.

From time to time panel practitioners receive from their insurance committee, through the pricing bureau, two sets of figures showing for each doctor, and for all doctors in the area, (1) the average number of prescriptions issued per person on list; (2) the average cost per prescription issued; and (3) the average total cost per insured person on list. If there is marked discrepancy between the individual figures and the average for the area, the Ministry of Health instructs a regional medical officer (often accompanied by a member of the panel committee) to call on the practitioner and ask for his explanation of the excess—for there is no case on record of an explanation being asked for the cost being below the areal average. If he gives a satisfactory explanation, for example, a diabetic case requiring insulin, or a bad case of cancer requiring many dressings, the matter there ends. But if the explanation is not thought satisfactory, the Ministry refers the prescriptions to the panel committee for investigation. The practitioner is invited to attend and the committee goes through the prescriptions in detail, looking out for the exceptionally costly preparations. The practitioner is asked to explain his method of prescribing, and to account for his costs being so much above that of his colleagues in the area. The difference in cost between what has been ordered and what might reasonably be considered suitable for such treatment is the cost that the panel committee will report to the Ministry, to the practitioner, and to the insurance committee, as the excess that the practitioner has imposed on the drug fund over and above the reasonable treatment of his patients. Local conditions and epidemics are taken into consideration as well as the age factor of patients. Both Minister and practitioner have the right to appeal to a court of medical referees appointed by the Minister, if either is dissatisfied with the finding. A Birmingham doctor was in December last found to have imposed £10 upon the drug fund in excess of what was reasonably necessary for the treatment of his patients. The excess was largely due to the prescribing of Brompton lozenges. He did not appeal against the surcharge.

Hypodermic Syringes for Asthma.

The regulations enjoin every practitioner on the panel to provide all proper and sufficient drugs for the treatment of his patients, but he may only order such appliances as appear in an authorised schedule. In these straitened times the authorities are unlikely to increase the size of this schedule unless it can be shown that hardship would result to patients through failure so to do. From several quarters has come a request to include hypodermic syringes for the self-treatment of asthma with suprarenal extract, as on a par with the supply of syringes already granted in the case of insulin for diabetes. No doubt the case for insulin was stronger as it can only be given hypodermically and life may depend on the proper dose at the proper time. But there is many an asthmatic patient who must pass hours of torture if a hypodermic syringe is not accessible; at present the patient must pay for it himself, it does not come out of the drug fund. The only difference it makes to the doctor is that if he orders the syringe on a panel prescription form, he is surcharged by the insurance committee through its pricing bureau and he may have difficulty in getting the cost back from his patient. It makes no difference to the approved society beyond the possible fact that in a case of hardship the society may agree to defray the cost of the syringe if it were shown that the patient was unable to afford it. Societies have funds available for other surgical appliances, trusses, and the like. But we think there is sound sense in being considerate to the asthmatic patient in this matter.

the bodies of a king and queen of Ur; a rib of Robert the Bruce; part of the "bowels that yearned" of Napoleon. Passing to its living guests, he welcomed especially Sir Hilton Young, who, as Minister of Health, was associated with one of the great adventures of medicine—the British Post-graduate Medical School; Sir Henry Wellcome, who had done more than any other living Englishman to advance research connected with medicine; and Sir Buckston Browne, to whose wisdom and foresight the College owed its research institute at Downe. Many great institutions died of dignity, some of rigidity. The College must not content itself with its old ideals of being an examining body with museum and library, but must ally itself as closely as possible with research.

The Duke of ATHOLL, in reply, described his experiences as a surgeon in the Sudan and at the hands of surgeons elsewhere. From earliest youth, he said, he had wanted to be a surgeon, and he was glad to be associated with the London Clinic and Nursing Home, which would, it was hoped, bring both medical and surgical skill within the reach of people of moderate means. He wished it to be understood that the Home was not a "tied house," since any consultant could attend patients there.—Sir HILTON YOUNG said that when he became Minister of Health he felt it his duty to give a conspicuous example of salubrity, but on shipboard had found it impossible to emulate all Lord Moynihan's hardy practices.

Lord DAWSON, proposing the health of the Hunterian Orator, emphasised the difficulties of giving praise to great men in their lifetime, as Mr. Trotter had suggested. Greatness was not always recognised; in 1872 even the Académie des Sciences refused to elect Charles Darwin because his theories were "a bad example which a body that respects itself cannot follow." Mr. Trotter, however, might at least be recognised as that rare thing, a master of thought and craft; a man with understanding of illness side by side with understanding of morbid processes; a man whose attitude foreshadowed the time when the artificial barriers between physician and surgeon would disappear; a man whose dislike of trappings and pursuit of truth made one say that the gods had called him.

Mr. WILFRED TROTTER, in thanking Lord Dawson, said that he stood there as a kind of surgical everyman and his own load of gratitude must be distributed to the surgical profession at large. He dated the rise of surgery from the time when the surgeon—hitherto bearing the same relation to the physician as the bricklayer's labourer bears to the architect—decided to have clean hands. To each of the professions the surgeon was indebted. The first successful amputation of the tongue was probably done under the auspices of the law. (As often happened, the operation was devised first and the proper use for it was discovered later.) From statesmen there was much to learn in the art of prognosis—the art of providing for the reconciliation of promise and fulfilment. The Services, too, had something to teach; for the science of strategy had been well defined as the discovery of design in things after the event. Could there be anything more valuable to surgeons in the not uncommon situation of explaining the successful operation to the bereaved? Finally, the Church had made its contributions to surgical art; but so far, said the Hunterian Orator in conclusion, he feared he had not acquired the clerical gift of being able to addres the same congregation twice in one day.

PANEL AND CONTRACT PRACTICE

Dangerous Drugs Acts Restrictions.

IF the Home Office withdraws a panel practitioner's authority to possess and supply dangerous drugs, does he ipso facto cease to be in a position to comply with his Terms of Service? The question has never been answered definitely in terms of general application. Some months ago [1] the Minister of Health took the lenient view that a particular practitioner could still adequately conduct his panel practice if certain other non-prohibited dangerous drugs were substituted and if he could on necessary occasions arrange for the coöperation of a colleague who was under no such disability. Recently in a Liverpool case the Minister has adopted the opposite course; the Dangerous Drugs Acts disability was one of several grounds alleged by the insurance committee against the panel doctor, not all of which were found proved; the Minister has decided to remove the practitioner from the medical list of the insurance committee.

The material clauses in the Terms of Service are paragraphs 9 (8), 9 (9), 9 (10), and 11 (1). They oblige the practitioner to supply, where requisite, drugs necessarily and ordinarily administered by a practitioner in person and drugs required for immediate administration; they oblige him to supply all requisite drugs to patients whom the committee requires him to supply; they oblige him to order such drugs as are requisite for the treatment of any patient and to sign the order with his own hand; finally they insist that, subject to certain specified modifications of the rule, the practitioner must give all treatment personally. In the Liverpool case the insurance committee set out, among other matters, the allegations that the practitioner had been convicted at th City Police-court (Liverpool) of several offence against the Dangerous Drugs (Consolidated) Regulations and that the Home Secretary had withdraw his authority as from March 18th, 1931, making thenceforth impossible for the practitioner to giv prescriptions for the purposes of those Regulation There was a further allegation that after that date th practitoner failed to order or supply drugs to thre specified patients as required by his Terms of Servic The facts of the conviction and the subseque Home Office action could not be controverted. regards the three named patients there was a dispute the insurance committee's case as to two of the thre broke down for want of evidence that the prohibite drugs had been necessary. The third patient ha died in May, *1931*; the practitioner produced letter from the patient's son expressing appreciatio of his father's medical treatment. The Inquir Committee reports that between Oct. 30th, 193 and Jan. 22nd, 1931, morphia grs. 76 had been pr scribed for this patient; after Jan. 19th, 1931, n morphia was prescribed for him until Feb. 27th, an thereafter only minute quantities were prescribe The tribunal had to say whether the Home Offic action in cutting off the power to prescribe morphi for this patient would bring about a failure to ord or supply drugs as required by the Terms of Servic The tribunal reports its inability to believe tha if the patient had been treated with morphia to th extent indicated by his prescriptions before Jan. 19t 1931, he would not have been prejudiced by i sudden cessation. For this reason and "in all th always causes the death of some abnormally susceptible individuals. The anticipated dangers of B C G have been amply demonstrated. Further, the history of the last three animals, cited by Dr. Griffith, which were exposed to natural infection should be a sufficient demonstration of the ineffectiveness of B C G. May I re-state the problem. Everyone who has attained adult years has been infected by the tubercle bacillus, but only a minority become diseased, because their resistance is not normal. If a normal immunity mechanism to the tubercle bacillus could be assured then tuberculosis would disappear. This can easily be achieved by a dead antigen. It is absolutely unnecessary to produce an immunity to withstand such an assaulting infection as the infection of millions of virulent bacilli as is done in the laboratory. Such infections do not occur in nature.

THE MECHANISM OF TUMOUR FORMATION.

To the Editor of THE LANCET.

SIR,—There are two clinical facts which may shed additional light on the interesting suggestions made by Mr. J. J. M. Shaw in his valuable paper on the Ætiology of Carcinoma.

(1) There are many patients with sallow, toxic faces and skin suggesting an anæmic state, but whose blood count is normal. These people's whole complexion and cutaneous state can be completely changed by permanganate lavage of the colon. This suggests that skin deficiency is related to intestinal toxæmia, and probably faulty intestinal absorption of essential biochemical elements. In this connexion his remarks about calcium and potassium are particularly interesting.

(2) These sallow skins, coated with sebaceous lipoid and other secretions, can be made to assume a temporary healthy appearance by pyretic treatment, or exercise hard enough to produce sweating. If treatment is prolonged this may become permanent. Analysis of the sweat will usually reveal a pH of about 6·6, which is more acid than the average. Also there is much lactic acid in the sweat.

A connexion between faulty skin and intestinal function and the genesis of epithelioma would appear to be a reasonable conclusion. The prophylaxis of this condition would then be the rectification of such faults of function and elimination.

I am, Sir, yours faithfully,

Portland-place, W., Feb. 11th, 1932. H. W. HALES.

REFERRED PAIN.

To the Editor of THE LANCET.

SIR,—The interesting inquiry into referred pain by Prof. H. H. Woollard, Mr. J. E. H. Roberts, and Dr. E. A. Carmichael, published in your issue of Feb. 13th (p. 337), calls for some comment. The discrepancy between the results of their experiments and some observations of mine[1] to which they refer appears to me to be due to certain differences between the methods we employed. Whereas they stimulated by compression the exposed trunk of the phrenic nerve in the neck, I stimulated the sensory terminals of the phrenic nerve on the under surface of the diaphragm in two patients with perforated duodenal ulcer and right shoulder-tip pain on whom I operated under spinal anæsthesia. Probably of more moment, however, than the difference between the methods of stimulation was the difference in the extent of subcutaneous anæsthesia induced. In the case they describe in detail as typical of nine experiments the authors infiltrated subcutaneously with novocain and adrenalin "an area about the size of a shilling internal to the acromio-clavicular joint," and found, on again lightly pinching the phrenic nerve, that there was merely a slight shifting of the area to which the pain was referred.

I should be very surprised if they had obtained any perceptible modification of the referred pain by so limited an anæsthesia. In my two patients I anæsthetised subcutaneously the whole area supplied by cutaneous nerves from the third, fourth, and fifth cervical segments. It should be noted that the *spontaneous* right shoulder-tip pain was abolished in one of my patients by this procedure, but was only modified in the other. The shoulder-tip pain *induced* by stimulating the under surface of the diaphragm with a swab was not abolished in either of my patients, but was greatly modified, as was shown by the much greater pain felt on a similar stimulation of the left side of the diaphragm. (The left shoulder-tip area was not anæsthetised.) I attributed my failure to obtain complete abolition of the referred pain in the shoulder to incomplete blocking of the third, fourth, and fifth descending cervical nerves. I should attribute the negative results of the experiments described by your contributors to the more limited area of subcutaneous anæsthesia that they employed.

These nerve-blocking experiments, however interesting and important though they are, form no essential part of the evidence for peritoneo-cutaneous radiation of pain. That process is made evident by the fact, as to which there is no dispute, that when the sensory fibres of the phrenic nerve are stimulated, the pain is referred *entirely* to the distribution of the third, fourth, and fifth cervical nerves in the shoulder-tip area, and is not appreciated by the sensorium as arising in the diaphragm.

I cannot refrain from expressing some astonishment at the first of the conclusions in the article to which I refer. The authors state that "the diaphragm behaves as a viscus, since light compression of the phrenic nerve occasions no sensation referable to its anatomical site." Surely it is characteristic of the abdominal viscera, as of the heart and lungs, that mechanical stimulation such as pinching when applied to them direct evokes no sensation of pain at all! The diaphragm, on the other hand, by reason of its somatic sensory innervation from the phrenic nerve, is exquisitely sensitive to mechanical stimulation.

It is, indeed, an arresting observation that stimulation of the sensory fibres of the phrenic nerve causes no pain to be felt in the diaphragm, but only causes pain in its metameric cutaneous nerve distribution. But it is not a new observation. And to say that the diaphragm in this respect "behaves as a viscus" betrays an obsession with the truth of Mackenzie's theory of a viscero-sensory reflex that one would hardly expect of such distinguished investigators. I venture to suggest that their experiments will merely focus attention once more on the profoundly important process of peritoneo-cutaneous (and pleuro-cutaneous) radiation of pain. We are only beginning to understand the nerve mechanism involved in that process, but I am sure that the phrenic nerve will prove to be the key to a proper understanding of the mechanism of referred abdominal pain in general.

CORRESPONDENCE

B C G VACCINE.

To the Editor of THE LANCET.

SIR,—All your readers will share in the feelings of sympathy with Prof. Deycke expressed in your leading article last week (p. 353). His terrible sentence, incurred in all probability through the error of a subordinate, forms a tragic culmination to a brilliant career spent in the service of humanity. The article however expresses no sympathy with Dr. Calmette; and yet he too has suffered, through the Lubeck disaster, what must have been a period of mental torture during the trial and, even now after an official vindication, the sort of distress which no man of his generous nature can avoid in contemplating so much sorrow and loss associated, through no fault of his own, with his great experiment. For a very great and daring experiment, that of Calmette in connexion with B C G, has been an experiment demanding faith and courage as well as enormous personal effort and drive. Great energy was needed to organise the production, standardisation, and distribution in vast quantities of a vaccine which has already been used for hundreds of thousands of children all over the world; to say nothing of the attempt to correlate and analyse the results reported by countless medical men, some capable and critical, some wild and enthusiastic, some hostile and prejudiced, but all requiring the individual attention of Dr. Calmette.

It is very difficult to control such an experiment, and the results so far recorded, while amounting to a vast array of figures, do not appear to satisfy the statistical mind. Yet the issue at stake is of sufficient importance to justify something more dynamic, on the part of British medical science, than the policy of "*festina lente*" which, as your article says, may sometimes be wisdom. Eleven years have passed since Calmette first attempted, on the grounds of numerous animal experiments, the daring step of putting his vaccine to the only crucial test, the inoculation of human infants against tuberculosis. So long ago as 1927, Prof. M. Greenwood expressed doubt as to the adequacy of the statistical value of the evidence adduced by Calmette to establish the immunising efficiency of B C G; but the figures, if not conclusive in favour of the vaccine, seem at least to have proved that it was innocuous. This point may now be regarded as settled by the admirable animal experiments of Dr. A. Stanley Griffith set forth in your last two numbers. I myself, after similar experiments on a smaller scale, and after a visit to Calmette's laboratory, felt so secure on this subject of safety that I advised my colleagues in Wales to try B C G in cases where infants were born of tuberculous parents. It may be added that, through the kind help of Dr. Calmette in sending his vaccine, a dozen infants have been so treated in and around Cardiff without untoward result and, so far, without the development of tuberculosis, although living in most cases with infected persons. It is not easy to find opportunities to use the vaccine, and our results have as yet no statistical value either way, beyond adding to the evidence in favour of the innocuity of B C G. "This," as your article puts it, "is the crux of the matter."

My study of the subject leads me to refer for a moment to the three questions posed in your leading article. Let us consider (1) whether the administration of a living but non-virulent strain protects in a way which a vaccine of dead organisms cannot? It seems to me that the bacteriological evidence favours this view, although the matter cannot be regarded as finally settled. It can perhaps only be settled, for man, by experiments on man.

This latter consideration gives point to the second question (2) whether the risks inherent in the use of living-culture vaccines cannot be guarded against with reasonable precautions in a well-organised [illegible] answer to this question is given [illegible] by the fact that B C G, distributed to many thousands of infants from the Pasteur Institute, has been used without bringing that Institute into discredit. My advice would be that those intending to try B C G should obtain their supplies from the Pasteur Institute rather than attempt, like Prof. Deycke, to have the vaccine made up locally.

Your third question, then, needs to be redrafted as follows: (3) Whether the dangers of tuberculosis in infancy are so great as to render the attempt at preventive inoculation advisable? At this point I must, in respect of the general population of these islands, part company from the views held, for France, by Calmette. I do not consider that there is any justification here for universal anti-tuberculosis vaccination of the children of healthy parents living in uninfected homes. Their risk is too small to necessitate such a step and their inclusion in an experiment could only lead to confusion. Nor, in view of the results of tuberculin tests in healthy persons, do I expect success from antituberculous inoculation in the prevention of adult phthisis. In the case of infants born into infected households, however, the risk of infection is very great, and the question of B C G inoculation does arise. My own inquiries lead me to think that fully half the tuberculosis of childhood and adolescence in England and Wales occurs in those who have been exposed to infection in their homes. The observations of Dr. Lissant Cox in Lancashire point strongly to the conclusion that infants and young children in infected families contribute an undue proportion to the tuberculosis incidence in the child population there. It is my opinion that the campaign against tuberculosis ought to be concentrated especially on tuberculous families, and that in this campaign the anti-tuberculosis vaccination of infants might play a useful part.

It may well be that a carefully controlled experiment, designed on lines acceptable to medical statisticians as well as the bacteriologists and clinicians concerned, and confined to the infants born to tuberculous parents, might give us the conclusively favourable results which are still required to ensure the wide employment of B C G in this country.

I am, Sir, yours faithfully,
S. LYLE CUMMINS.

Tuberculosis Department, Medical School, Cardiff,
Feb. 15th, 1932.

PREVENTIVE INOCULATION AGAINST TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—It does not seem to me that any reasonable person can think the B C G method a desirable way to immunise human beings against tuberculosis. It is beset with the dangers always associated with a method of immunisation with a living antigen which between a school advocating small doses and another pinning its faith to intensive treatment. So far as I was myself concerned, while I pointed to the undoubted effects which can be produced by doses which may be described as not only relatively but absolutely small—in that they are near the point when demonstrable effects no longer occur—I was concerned rather with an attempt to lay down principles than to deal with the exact size of doses.

A great deal of recent writing on the subject is concerned with getting this or that amount of radiation, a greater or less number of erythema doses, "into the tumour," as the phasing goes. The underlying idea still seems to be that of the "lethal dose," although it is admitted that, even with the most intense applications, there is no certainty of killing every cancer cell. It seems to be held by this school that any future increase of voltage, by enabling a relatively greater amount of radiation to be delivered within the tumour, will necessarily improve results. It is my belief that the tissue reactions which are excited by X rays are of no less importance than their direct depressant effects upon malignant cells. And it is as certain as anything can be that, at any rate in the hands of some of its advocates, a single course of intensive treatment results in permanent damage to previously healthy tissues in the neighbourhood of the growth. The reaction may in rare instances accomplish the eradication of all cancer cells before the reacting tissues settle down into a permanently enfeebled state, from which further X ray treatment cannot raise them. In certain desperate cases such "forlorn hope" methods may therefore be justified. But to advocate similar dosage as a routine cannot be right.

In the course of my paper I made the following statement :—

> "With the exact details of dosage in various malignant conditions I am not here concerned. What I am contending for is the recognition of certain fundamental truths: that radiations act chiefly as agents for stimulating the resisting powers of the body; that it is impossible by any practicable radiation dosage to ensure in a few days or weeks the death of all cancer cells; and that methods of treatment which aim at conserving tissue response are alone sound in principle."

By "small doses" are usually understood such as were given twenty or more years ago. They produced results, but I never made any suggestion that we should adopt them as a standard. I am prepared to believe that the best dosage may be nearer to that of the big dose school of to-day than to that commonly used in the second decade of this century. What I am not prepared to believe is that the principle of the *therapia sterilisans magna*, which has failed signally in other branches of medicine, can be successfully applied in the X ray treatment of cancer.—I am, Sir, yours faithfully,

F. HERNAMAN-JOHNSON.

Brook-street, Grosvenor-square, W., Feb. 10th .1932

BRILLIANT GREEN FOR SYCOSIS.

To the Editor of THE LANCET.

SIR,—Dr. Garrod has had the great courtesy to send me his interesting and valuable paper on the "Chemical Prophylaxis of the Streptococcal Infections." His and Prof. Senin's technical conclusions will be accepted with gratitude by all thinking men. Lately my work has been chiefly directed to calling attention to the fundamentals which govern the effective activities of irritants upon the skin. Incidentally micro-organisms come into the picture. The suitability and convenience of the means used for their control should apply equally to the investigator as to the clinician.

Alcohol is cleanly and mildly antiseptic; frequent applications of it are harmless to the skin but inimical to bacteria. Upon protein the primary physical effects of alcohol, iodine, picric acid, tannic acid, &c. are similar, but they vary in degree and some have greater powers of penetration. Their first effect is what is called astringent, which is another name for flocculation of the superficial tissues. The sum of these effects makes these medicaments suitable for different stages in the many varieties of skin troubles. A knowledge of these factors is essential to the dermatologist if he is to apply remedies successfully. It would have been very helpful if Dr. Garrod had elaborated this aspect of the subject, when dealing with the numerous germicides mentioned in his paper.

Reverting to the chief theme of my letter, which was the cure of the superficial folliculites, coccigenic sycosis in particular (and in this connexion I use the word "cure" intentionally), neither a tendency to lean upon tradition, nor fashion as Dr. Garrod says is common, in his original article, nor yet a slothful attitude in accepting new ideas, is one of my many failings. May I point out to him that he has experimented with surgical spirit, which is alcohol diluted 1 in 5 of water. I use and advise pure alcohol, a very different proposition. Alcohol is not the only ingredient and the other details of the treatment must be fulfilled. Whether his patients are likely to prefer a speedy and not unsightly mode of treatment to one which at least produces an apparently alarming and certainly disagreeable appearance, I leave to Dr. Garrod's discretion to decide.

I am, Sir, yours faithfully,

Wigan, Feb. 12th, 1932. R. PROSSER WHITE.

VENESECTION IN HEAT-STROKE.

To the Editor of THE LANCET.

SIR,—The annotation on Heat-stroke in your last issue (p. 358) recalled to my memory a case I had many years ago when I was surgeon to the R.M.S. *Orizaba*, Orient Line, on a voyage from England to Australia. When passing through the Red Sea I was called to see a steerage passenger. I found a stout, middle-aged Irish woman with consciousness completely lost, flushed face, skin very dry and hot, stertorous breathing—temperature between 108° and 109° F. I tried every remedy I knew of and found recommended, but it was all in vain, so at last I decided to try venesection and truly the result was wonderful. Within a short time the patient was conscious and next day the temperature was nearly normal. It is a pity venesection is not more practised.

I am, Sir, yours faithfully,

J. JOHNSTONE REDMOND.

Elm Park-gardens, S.W., Feb. 15th, 1932.

PANEL HEATING OF HOSPITALS.—The new Benito Mussolini Tuberculosis Hospital in Rome which it is expected will be opened about the middle of next year, is to be warmed on the British panel system. The hospital will contain nine wards with 2500 beds, and will thus be one of the largest institutions of its kind. The system has been adopted on the recommendation of a committee of investigation which examined the system as installed at St. Bartholomew's and University College Hospitals and the Harrow Hospital memorial extension. Dr. Eugenio Morelli, the director of the hospital, afterwards tested it at one of the smaller institutions under his charge, and found that it worked perfectly in a room with open windows and is thus especially suited for sanatoriums.

Your contributors suggest that the nerve-blocking experiments of Lemaire and of Weiss and Davis, if confirmed, would render still more insecure the theory of referred pain which is generally accepted. They do not make clear the fact that Lemaire and Weiss and Davis all believed that their experiments supported Mackenzie's theory. I have dealt with that belief in my book, and will not repeat the argument here.

Finally, if your contributors have knowledge of any sound experimental or clinical evidence in favour of Mackenzie's theory of a viscero-sensory reflex, I would most earnestly ask them to make it public.

I am, Sir, yours faithfully,

Manchester, Feb. 14th, 1932. JOHN MORLEY.

CARDIOVASCULAR EFFICIENCY IN RHEUMATIC CHILDREN.

To the Editor of THE LANCET.

SIR,—Many clinicians will be grateful to Wing Commander Treadgold and Squadron Leader Burton for their work, published in your issue of Feb. 6th (p. 277), on the size of the heart in relation to cardiovascular efficiency. This work has been confined, I gather, mainly to healthy, or presumably healthy, young adults. During the last four years I have carried out a series of similar tests in a large number of children attending a rheumatism supervisory centre. The original details were given in a paper read to the children's section of the Royal Society of Medicine in Feb., 1929, and are also published in the report of the school medical officer for the County of London for that year.

In children the first problem is to determine what the size of the heart should be. Where there is a gross enlargement, as in the cases of old adherent pericarditis, or severe valvular disease and the cardiac impulse is very forcible, no difficulty is experienced. But in those vital early cases I find it impossible to say now, after a careful examination of some 3000 cases, where the apex-beat should be at any given age. I place very little value on percussion of the right side of the heart in children, except for very considerable changes. In a series of 243 cases examined for pulse changes it was found that :—

45	had a recumbent pulse-rate between	70–80
67	” ” ” ”	80–90
78	” ” ” ”	90–100
63	” ” ”	over 100

whilst the standing pulse-rate of this group was :—

17	between ..	70–80	76	between ..	90–100
52	” ..	80–90	100	were over ..	100

In a group of 187 cases, whose cardiac efficiency was estimated by the methods previously mentioned, the number rated below—

0	was	6	4	was	13	8	was	13
1	”	3	5	”	10	9	”	21
2	”	3	6	”	9	10	”	29
3	”	7	7	”	8	over 10	”	65

The number whose critical figure was 13 or over was 70, and this corresponds to the number of "heart" cases, 77, in the series.

The point I am trying to make is that in spite of adverse criticism the use of cardiac efficiency tests, *together* (and this is vital) with clinical signs and symptoms, affords a valuable means of assessing the progress of a cardiac case. The test has the fallacy of all numerical measures, but it has the merit of simplicity, and of being able to be performed without special apparatus in the consulting room or bedside. In another series of 208 cases analysed and divided into three groups :—

(*A*) 108 cases with definite evidence of carditis.
(*B*) 22 ” ” cardiac irritability, but no carditis.
(*C*) History of rheumatism, but no cardiac disease.

The following findings emerged :—

Resting pulse-rate.	*A.* (*a*) Active.	*A.* (*b*) Healed.	*B.*	C.
Over 100	46	81	40	80
Under 100	54	19	60	20

Definite cases.	Over 8.	Under 8.
Active	27	73
Inactive	75	25
Group *B*	40	60
Group *C*	80	20

The effect of exercise on the pulse-rate was :—

	Active.	Healed.	*B.*	C.
Increase in pulse-rate under 30	53	28	56	78
” ” ” over 30	47	72	44	22
Return to standing pulse-rate in 120 sec.	28	18	30	17
Pulse-rate raises after 120 ..	21	11	15	6

We have also found that the temperature o children attending the clinic is as often 99·2° F as under this figure—and we have come to regar a temperature of 99°, unassociated with any c the usual signs and symptoms of rheumatic feve as being normal under conditions of examinatio We have found that these emotional children hav unstable temperatures ; it is of course well recognise that rheumatic and choreic children are often of th emotional type.

In our series the blood pressures have all bee taken. A very usual systolic blood pressure is 10 while the diastolic average is 65. In the sever cases of mitral disease we have had pressures of 1 recorded, with corresponding rises of diastolic readin

The cases which have given us the greatest anxie have been the simple tachycardias with a mild fev I find that it is clinically impossible to separate the cases from rheumatic myocarditis, and I hold th it is my duty to treat them as such for a period say, four to six months. If, at the end of this tin their condition is unaltered, and their electi cardiogram negative, the choice must be ma between valetudinarianism and the neglect of wh may turn out to be a serious cardiac lesion. mention these cases, because unfortunately this one of the groups where cardiac efficiency tests m fail—and often do. By tachycardia I mean a pul rate of 105 or over in a child of 10, which runs up 140 or more on exertion.

I am familiar with Sutherland's and Schlesinge work on the variation of pulse in the waking a sleeping child, and it may be that this method m be of service in helping us to estimate the activ of the cardiac lesion. I must say that the determi tion of cardiac efficiency, and the presence or abse of active carditis seems to me to be one of the m urgent problems in clinical medicine, and I thi it is one which may be solved eventually by simple cardiac methods described by Wing Co mander Treadgold and Squadron Leader Burton

I am, Sir, yours faithfully,

Harley-street, W., Feb. 12th, 1932. GERALD SLOT

X RAY DOSAGE IN MALIGNANT DISEAS

To the Editor of THE LANCET.

SIR,—In your issue of Jan. 31st (p. 254) refere is made to a discussion on this subject which to place at the Section of Radiology of the Royal Soci of Medicine on Jan. 15th. If I may be permitted criticise your annotation, it seems to me that t much stress is laid in it on the alleged oppositi

PUBLIC HEALTH SERVICES

LONDON COUNTY COUNCIL.

NUAL REPORT OF THE MEDICAL OFFICER OF HEALTH FOR 1930.

(Concluded from p. 162.)

EX-POOR-LAW HOSPITALS.

AT the end of 1930 the general hospital service mprised 27 acute hospitals, 13 hospitals and titutions for the chronic sick, 2 convalescent pitals, and 2 colonies for sane epileptics. The ite hospitals suffer from noisy surroundings, ufficiency of isolation wards, and lack of means the classification of patients. Ultimately some l have to be replaced by more modern buildings. the past some of these ex-poor-law hospitals have n overcrowded at a time when others had empty ls, owing to the legal obligation to provide treat-nt without delay for destitute persons. These pitals could not, like voluntary hospitals, select ir patients and close their doors when their beds re full, there has not been convalescent accommo-ion available for them, and the bed space per ient was generally too low. The demand for pital accommodation increases, and will increase re rapidly, now that the pauper restriction has n removed. There have also to be considered need for more adequate provision for the so-called ddle class, and the large increase in street casualties recent years. Sir F. Menzies pays a tribute to the endid work done by these poor-law hospitals, hough there was much variation in the policy rsued by the various boards of guardians. The blem now, put quite briefly, he says, is to find the t scheme for the prevention and treatment of ease of the people of London. The classification the many types of patients is a big task. For ample, some require dormitories, day-rooms, and rk-places; others dormitories and dining-rooms; ne must have their meals in the wards, and there sick children, maternity patients, and the blind d mental patients to be considered. At the time writing the report a comprehensive survey (outlined a previous article) was in progress in order to olve a scheme for the better utilisation of the commodation.

DISTRICT MEDICAL SERVICES.

These have been continued as before, pending view and consideration of the best system. There e 126 medical relief districts in the county, and 108 the district medical officers are part-time practi-ners under no medical supervision except in ackney, where the eight medical officers act under e supervision of the medical superintendent of the spital. In the remaining 18 districts, the district dical officer is a whole-time official acting under e supervision of the medical superintendent of the spital, and usually also a medical officer of the pital. In most of these ex-poor-law hospitals an t-patient department has arisen to deal with sualties, after-care of former in-patients, and pro-ion of antenatal and postnatal care for maternity [illegible]. For instance, out of 29 hospitals, 27 provide r casualties, 24 for the after-care of former in-atients, and 20 have antenatal clinics. It is ggested that in the future the scope of these out-atient departments will be extended.

MATERNITY AND INFANCY.

The quality of maternity accommodation in the transferred general hospitals varies from a fully equipped maternity block with 36 beds and 3 labour wards to quite primitive conditions. The wards at one hospital have been closed, and all maternity wards are being surveyed with a view to gradual improvement. The demand for maternity beds is increasing. The response from the patients to the establishment of antenatal clinics is remarkable, and these clinics have the advantage of being under the same roof as X ray and other departments. Before transfer, obstetrical consultants had been appointed to 9 of the hospitals, and the extension of this provision is being considered as part of the general question of supplying consultants for the council's hospitals.

The healthy children under 3 years in the Council's care at the end of the year numbered 706, of whom 442 were separated from their parents. These children require different accommodation in the first year of life, in the second year of life, and in the third year, when they are becoming more active and independent At the present time each nursery accommodates all three groups.

MENTAL.

The late boards of guardians had observation wards for mental patients in 21 hospitals and institutions. These wards on the whole fell short of the minimum standard for good classification and efficient treatment. Only 5 of the hospitals had a complete unit with two wards, day-room, airing court, and padded cells. In future schemes the aim will be to have larger and more efficient units. At present only 2 of the hospitals with mental wards have a mental specialist as consultant. Since September, 1930, trained mental welfare workers have been acting as home-visitors for two of these hospitals. X ray apparatus is or will be installed in most of the hospitals, and during the year Dr. Stanley Melville, who has been appointed consulting radiologist, has made a careful review of the plant in use. His report emphasises the fact that nowadays the radiologist at each hospital should be adequately trained and experienced in this special work.

ADMINISTRATION.

It is expected to effect considerable economies in the purchase of medical supplies, and a sample room has been set aside in the County Hall, where the contract standard samples and samples of instruments are available for inspection. Unusual and expensive instruments will also be kept in the sample room and be available for loan to the hospitals.

Special accommodation has been set aside for children suffering from chicken-pox, whooping-cough, mumps, and measles, and in order to deal with a long waiting-list of school-children needing operations for enlarged tonsils and adenoids arrangements have been made for these children to be operated upon in certain of the general hospitals. As regards convalescent accommodation, there are now available 500 beds at Queen Mary's Hospital, Sidcup, which was opened by Princess Mary in July, 1930; 320 beds at St. Benedict's Hospital, formerly known as Tooting Home; and the Council have acquired Heatherwood Hospital, Ascot (136 children's beds), from the United Services Fund, along with its obligation to the children of ex-Service men.

THE SERVICES

ROYAL ARMY MEDICAL CORPS.

Lt. (on prob.) H. V. Tighe resigns his commn.

C. W. A. Kimbell is granted a temp. commn. in the rank of Lt.

ARMY RESERVE OF OFFICERS.

Capt. N. H. Smith, from Supp. Res. of Off., to be Capt.

TERRITORIAL ARMY.

Lts. R. I. Poston and W. F. Mulvey to be Capts.

INDIAN MEDICAL SERVICE.

The undermentioned appts. are made:—To be Capts. (on prob.): Capt. R. A. Wesson, W. Happer, and J. J. Quinlan. To be Lts. (on prob.): R. J. Jarvie, F. A. B. Sheppard, P. E. Sweeney, M. Sendak, and W. A. N. Marrow.

ROYAL AIR FORCE.

R. L. Raymond is granted a short service commission as a Flying Officer for three years on the active list.

ROYAL AIR FORCE RESERVE.

The undermentioned Flying Officers are promoted to the rank of Flight Lt.: W. J. Hutchinson, D. Magrath, W. A. Beck, and M. D. Rawkins.

DEATHS IN THE SERVICES.

Lt.-Col. Charles George Spencer, late R.A.M.C., died at Queen Alexandra Military Hospital on Feb. 8th, aged 63. A graduate of the University of London, he joined the medical department of the Army as Lt. in 1893, and served in the Ashanti Expedition of 1895–96 (Star) and in China in 1900 (medal). In 1905, when he had reached the rank of Major, he became professor of military surgery at the Royal Army Medical College, a post which he held till 1910. He retired from the service three years later, but was recalled to the active list on the outbreak of war in 1914. Lt.-Col. Spencer was the author of Gunshot Wounds, a book, published in 1908, which showed keen observation and care, and which has been found useful by the civil practitioner as well as the military officer. He also contributed to Choyce's System of Surgery and to Latham and English's System of Treatment, and made some useful communications to the medical press.

Dr. A. F. H. Stewart, M.O., St. Vincent, has been appointed Government M.O., Trinidad.

OBITUARY

WILLIAM BILLINGTON, M.S. Lond., Ch.M. Birm., F.R.C.S. Eng.

THE Birmingham School and the Queen's Hospital in particular has suffered another severe blow in the death on Feb. 7th of Mr. William Billington, professor of surgery in the University and senior surgeon to the hospital. He had been in failing health for several months past, but in spite of increasing disability he carried on his work courageously almost to the last.

William Billington was born at Sandbach, Cheshire, in 1876, was educated at the grammar school there and then at Wellington (now Wrekin) College, Salop, where he became head of the school and secretary to its master and founder, Sir John Bayley. He began his medical study with a scholarship at Mason College, where he gained numerous distinctions including that of Ingleby scholar in gynæcology. In 1899 he graduated M.B. Lond., with first-class honours and the Gold Medal in gynæcology. After serving as house physician to Dr. Arthur Foxwell, he was then in succession house surgeon to Prof. Jordan Lloyd at the Queen's, and resident pathologist at the General Hospital. In 1902, after some post-graduate study in London and taking higher surgical diplomas, he was appointed surgeon to out-patients at the Queen's, becoming full surgeon in 1913. In the following year he joined the staff of the 1st Southern General Hospital, with charge of the centre for jaw and facial injuries. Here, in coöperation with his dental colleagues, Mr. Harold Round and Mr. A. H. Parrott, he did much bone-grafting of the lower jaw and facial repair, original work which was not only of value to wounded soldiers, but has proved equally beneficial in civilian practice.

PROF. BILLINGTON.

[*Photograph by H J. Whitlock.*

Mr. Billington was largely instrumental in founding, in 1913, St. Chad's Hospital, the first institution of the kind in the country, to provide expert medical and surgical treatment and skilled nursing for the large class of patients who cannot afford high fees and yet do not wish to go into the public hospitals. Practica experience there convinced him that with prope organisation paying hospitals can be made a succes and satisfy consultant, practitioner, and patient He devoted much time and thought to hospital administration. As chairman of the medical committee of the Queen's Hospital, he took a leading part in its extension, and in raising the necessary funds. He worked untiringly and unselfishly in support of the proposed University hospital centre.

In 1924 came his appointment to the University chair of surgery. He had long been known as a clear convincing speaker—in 1911 he had delivered a series of addresses on surgical topics in the United States of America—and as an able and lucid teacher of students. He was popular with his classes, and a pillar of strength in the medical school. As a surgeon he was cool and dexterous; his technique was neat with a scrupulous regard for detail. He had made a special study of movable kidney and devised a new method of renal fixation. He had also a large experience of chronic ulcer of the body of the stomach for which he advocated a trial of double gastro-enterostomy combined with entero-enterostomy. As a colleague he was helpful in advising and guiding his juniors. Outside the hospital he had a large consulting practice which left him little leisure for other pursuits, but he loved the country and enjoyed an occasional day's shooting or fishing.

In 1906 Mr. Billington married Miss Winifred Cooke, of Edgbaston. Their daughter and two of three sons are studying for the medical profession.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

ANGEROUS DRUGS ACTS AMENDMENT.

x the House of Lords on Thursday, Feb. 11th, ill was introduced to amend the Dangerous Drugs s. The measure was read a first time.

CHILDREN AND YOUNG PERSONS BILL.

n Friday, Feb. 12th, the House of Commons sidered the Children's and Young Persons Bill. Ir. **Oliver Stanley**, Under-Secretary for Home airs, in moving the second reading of the measure, l that its main object was to amend the existing contained in the Children Act, 1908, and other tutes relating to the protection of neglected dren and young persons and the treatment of ng offenders. The Bill would make a beneficial ration in the social life of the country by which was hoped to reduce the criminal population. had to confess that the measure was one of the st examples of legislation by reference that he l ever seen. It was intended that it should be owed by a Consolidating Act in which could be hered together all the provisions dealing with the ld and the young offender. Under the Bill there ld be magistrates chosen from a special panel, cted for their knowledge and of interest in work his kind. It would be left to the Lord Chancellor rescribe rules for the selection of a special panel of gistrates to sit in Juvenile Courts, and a special irman to preside. Great importance was attached the separation in venue of the Juvenile Court n the Adult Court. The right of the parent to ect to a child being dealt with in a Juvenile Court s to be done away with, but the right of the young son to object himself and to claim to be tried in ther place would remain. Special arrangements e made in regard to the Metropolitan courts. Bill extended the jurisdiction of juvenile courts r young offenders, raising the age from 16 to 17. change was made in the case where a young son charged with an adult was tried in an adult rt, but power was given to the adult court to nit the young offender to a juvenile court for tment.

WHIPPING.

ne of the most important changes was the lition of certain powers of the court to order ipping. There was no mention of whipping in Bill at all, but power would still remain to send boy over 14 to Quarter Sessions to be tried on charge where Parliament had made whipping statutory punishment. Whipping as a punishnt had been falling into disuse. The annual res of whipping had fallen from 2079 in 1913 to y 130 in 1930, and although these figures had been lysed it was quite impossible to trace the residue any particular crime that would enable then to that the magistrates' experience had shown that, hough whipping might not be an adequate punishnt in all circumstances, it was useful under this that conviction. There was all the difference in world between being whipped by a school-master being idle and being whipped by a policeman. ear, hear.) It was one of the most revolutionary posals of the Act of 1908 that for the first time it owed the courts to entertain the cases of children o had committed no offence but whose circumnces made it desirable that they should receive tection. This right was given in respect of children to the age of 16, with regard to specific categories home circumstances, including destitution, drunken nts, sexual offences, prostitution, or wandering thout parental control. By this Bill it was proposed extend the age from 16 to 17 and to abolish those cial categories and substitute for them one wide definition which would bring in a number of cases that were brought in to-day only by a very great strain of the law. There was no question of ignoring the parent and substituting the State, because the fundamental basis of these cases was that parental control had been abdicated.

REFORMATORY AND INDUSTRIAL SCHOOLS.

The Bill also provided an alteration in connexion with the reformatory and industrial schools, which in future would be known as "approved" schools. Both these types of school were now connected with the State, and both could be used. The industrial school could be used for neglected children, for offenders under 12, or for first offenders up to 14; the reformatory school must be for all other types of offenders. The distinction between the two types of school was largely artificial; both classes of children had to suffer the withdrawal of their liberty, and it was proposed to abolish the distinction between the two types of school and put them both under the head of "approved" schools. The period of detention in future would be automatic. For a child under 14 it would be for three years, or in any case until the child had reached the age of 14; in the case of the young person it would be for three years, but not in any case beyond 19. For both children and young persons it would be possible, with the assent of the Home Secretary, to detain them for another six months, if they required further vocational training before it was possible to find them employment. This automatic period would give a chance of experiment in short term detention in the schools. The Home Secretary would have power to license at any time after six months, and it was intended to try with the most suitable type a short period of training for six months, or some period of that kind.

STREET TRADING.

Part III. of the Bill gave effect to the recommendations made in the third report of the Child Adoption Committee for the registration and inspection of voluntary homes. Part IV., which dealt with the employment of children and young persons, was largely reprinted from the Education Act, 1921, with minor drafting amendments. There was one alteration of some importance which affected street trading. Under the Education Act, 1921, street trading was prohibited up to the age of 14, and regulated by the education authorities between the ages of 16 and 18. It had been decided not to regulate under this Bill the employment of boys and girls in unregulated employment. He recognised that that would cause disappointment in some quarters, but this question was not related in any way to the purposes of the Bill. It was estimated that the Bill would save the State £8000 a year. (Cheers.)

OMISSIONS REGRETTED.

Mr. R. J. **Davies** said that the Opposition welcomed the Bill. He regretted that the Bill did not provide for the establishment of observation centres which have produced very good results in Belgium.

Viscountess **Astor** said she regretted that the Government have not included in the Bill some of the recommendations of the committee on sexual offences against young persons. That type of crime was increasing, and those guilty of it often received inadequate sentences. It was estimated that 400,000 children were employed in unregulated trades, and some of them worked 72 hours a week. She thought that they ought to fight the opposition of people who wanted to make money by employing children for 72 hours a week. The House of Commons ought to insist on the hours of employment of children between the ages of 14 and 16 being regulated.

Dr. **Salter** said he understood that great efforts

The hours of awakening patients at the 28 general hospitals were found to vary considerably. At ten of them patients were awakened at or before 5 A.M. It is now proposed that the awakening hour should not be before 6 A.M., and that all hospitals should be raised to this standard as staff becomes available. Incidentally, the report shows that the settlement of standard conditions for the various grades of nurses has already had its effect in increasing the applications for entry as probationers in the Council's service. The creation of a nursing staff common to the whole of the Council's hospitals has provided wide facilities for training and experience and opportunities for promotion more extensive than those in any comparable service.

EX-M.A.B. HOSPITALS.

Sir F. Menzies points out that when the special hospitals were transferred from the M.A.B., the Council took over a highly organised system of hospitals, the administration of which had, as a result of a natural process of development over a long period of years, been coördinated, and that all that was necessary was to adapt the methods under which they had been administered to the Council's system, a comparatively simple process. Amongst the research work in progress at the infectious hospitals are a trial of vitamin A concentrate in the prevention of secondary infections, such as middle-ear disease, under the supervision of Prof. S. J. Cowell; a trial of the aspiration method of treating laryngeal diphtheria, and the study of the heart in diphtheria by means of the electrocardiograph. Convalescent serum is in successful use for the prevention of measles, and encouraging results are reported from the treatment of parkinsonian cases with the dried extract of stramonium (U.S.A. pharmacopœia). Cases of acute poliomyelitis are sent to the Western Hospital, and the absence of any epidemic prevalence during the year is indicated by the fact that only five cases were admitted. Small-pox cases admitted to the "River hospitals" numbered 6170, of whom 19 died. Nine babies were born in hospital; 35 babies not suffering from small-pox were admitted with variolous mothers, and five mothers not suffering from small-pox with variolous babies. During the year four cases of acute encephalomyelitis occurred, of which one only had been recently vaccinated. Mr. M. S. Mayou, F.R.C.S., reports that 196 babies and 113 mothers were admitted to St. Margaret's Hospital for ophthalmia neonatorum. The number of damaged eyes was less, but still "far too many." Some cases are admitted with the cornea damaged by too strong nitrate of silver or perchloride of mercury. Many midwives visited the institution during the year, but not a single medical student. Mr. Mayou deplores the absence of the latter.

SYPHILITIC MOTHERS.

Mr. John Adams, F.R.C.S., reports on the work of Thavies' Inn V.D. Hospital. Three patients were confined of macerated babies a few days after admission. All babies born from syphilitic mothers were discharged with a negative Wassermann test, except four, who left within a month. Of the latter, two had out-patient treatment and became negative, and the other two were lost sight of. Many children born of syphilitic mothers have been under observation since 1917, and had blood tests from time to time. All have appeared healthy, and none has shown any signs of syphilis.

TUBERCULOSIS.

Dr. James Watt, chief medical officer, tuberculosis service, reports that 3228 cases of pulmonary tuberculosis were admitted to the hospitals, and that the average duration of stay was longer than in the previous year. He states that in other countries the duration of stay in hospital is 50 per cent. longer than in England. The recognition during the last ten years of the poor after-results of sanatorium treatment, he says, has led to a revision of methods. A much larger proportion of cases are being treated by surgical methods, and when it is more widely recognised that thoracoplasty, generally reserved for hopeless cases, gives as high a proportion of cases alive after five years, as ordinary sanatorium treatment can give for all cases, early and advanced, it is certain to be used more extensively. He also refers to the promising results obtained from the injection of gold salts, and to the need for further research as to the action of this remedy and the best dosage. He recommends the institution of out-patient clinics at certain of the Council's hospitals for the continuance of pneumothorax treatment. The immediate results of treatment on discharge from Pinewood and King George V. Sanatorium were apparently satisfactory, but, if we are to judge by past experience, 50 per cent. of the patients will die within five years, and only 25 per cent. be fit for work. It may be, he thinks, we have paid too much attention in the past to the disappearance of symptoms and physical signs, and too little to X ray pictures of the condition of healing of the lungs.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDE

FEB. 6TH, 1932.

Notifications.—The following cases of infectiou disease were notified during the week:—Small-po 57 (last week 49); scarlet fever, 1485; diphtheri 1015; enteric fever, 36; pneumonia, 1742; puerpera fever, 55; puerperal pyrexia, 99; cerebro-spin fever, 48; acute poliomyelitis, 6; acute poli encephalitis, 4; encephalitis lethargica, 7; continue fever, 1; dysentery, 20; ophthalmia neonatorum, 9 No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Feb. 9th–10th was as follows: Small-pox, 105 under treatment, 4 under observation (last week 110 and 3 respectively); scarlet fever, 1199; diphtheria, 1502; enteric fever, 10; measles, 905; whooping-cough, 334; puerperal fever, 13 (plus 10 babies), encephalitis lethargica, 220; poliomyelitis, 4; "other diseases," 241. At St. Margaret's Hospital there were 15 babies (plus 9 mothers) with ophthalmia neonatorum.

Deaths.—In 117 great towns, including London, there was no death from small-pox or enteric fever, 44 (15) from measles, 7 (1) from scarlet fever, 50 (11) from whooping-cough, 36 (7) from diphtheria, 53 (8) from diarrhœa and enteritis under two years, and 278 (81) from influenza. The figures in parentheses are those for London itself.

The reported deaths from influenza are still falling, but the total deaths for the year so far amount to 1732 against 1126 for the corresponding period of 1931. Of the great towns Birmingham again stands highest with 12 deaths from influenza, Manchester following with 8, Croydon, Bradford, Sheffield, and Swansea, each with 6. Manchester reported 11 deaths from measles, Stoke-on-Trent 5. Whooping-cough accounted for 4 deaths at Liverpool, 3 at Manchester.

The number of stillbirths notified during the week was 273 (corresponding to a rate of 41 per 1000 births), including 41 in London.

MONDAY, FEB. 15TH.

Sterilisation of the Mentally Unfit.

Captain WATT asked the Minister of Health if. in view of e social evil arising out of unrestricted propagation amongst entally defectives and the consequent increase in the umber of such persons, he was prepared to investigate the estion of the sterilisation of the mentally unfit and. desirable. to introduce legislation to eradicate the evil.—r. ERNEST BROWN (Parliamentary Secretary to the inistry of Health) replied: The desirability of legislation ould not, in my right hon. friend's view. be determined ntil there has been a full and authoritative inquiry into he problems of mental deficiency. in which sterilisation is nly one of several inter-related questions. But as a st step towards such an inquiry, my right hon. friend oposes to arrange for a preliminary investigation of the ientific issues involved.

Dr. MORRIS-JONES asked if the right hon. gentleman would nounce the names of the members of the Committee, d Mr. Brown replied that he had nothing to add to his swer.

Sale of Proprietary Medicines.

Sir JOHN HASLAM asked the Secretary to the Treasury he was aware that certain makers of proprietary medicines ered their products to the public at one fixed retail ice, although in certain cases the goods bore no patent edicine stamp and in other cases the self-same article had e full Government stamp; and whether he would take eps to prevent this evasion of the law and loss of public venue.—Major ELLIOT (Financial Secretary to the Treasury) plied: I assume that my hon. friend is referring to cases ere a medicine is sold unstamped by duly qualified emists and druggists under the conditions of the statutory emption from Medicine Stamp Duty in favour of "known, mitted, and approved of" remedies but is properly amped when sold by other persons than qualified chemists d druggists. I would explain that the question of the ices charged is not a matter in which I can interfere and am not aware of any infringement of the law in such cases.

TUESDAY, FEB. 16TH.

Alleged Illegal Detention of a Girl.

Mr. WEDGWOOD asked the Minister of Health whether s attention had been called to a recent case of illegal etention of a so-called mentally deficient girl; whether y other persons were detained by the same people; and at was the practice with regard to inspection of homes for phans or feeble-minded persons.—Mr. E. BROWN (Parliamentary Secretary to the Ministry of Health) replied: y right hon. friend's attention has been called to the case. is girl was not certified as mentally defective, nor regarded subject to be dealt with under the Mental Deficiency Act. ere is no evidence that other persons are being detained the same people. All premises certified for the reception mental defectives are regularly inspected by the Board of ontrol.

MEDICAL NEWS

---

niversity of Cambridge.

On Feb. 13th, the following degrees were conferred:—
M.D.—C. F. Brockington.
B.Chir.—G. D. Kersley and T. C. Larkworthy.

oyal College of Physicians of Ireland.

At a meeting of the College on Feb. 5th the following were dmitted to membership: James Andrew Donnelly Deeny. D., Gerald Cecil Dockeray. M.B., Vincent Cornelius lis, *M.D.*, Maurice Fitzgerald Nash Griffin. R.A.M.C., nna Mary Elizabeth McCabe, M.B.. Desmond Kyran lrany, M.B., Gerard Thomas O'Brien. L.R.C.P., and lan Herbert Thompson, M.B.

ritish College of Obstetricians and Gynæcologists.

At a recent meeting of the Council, with Prof. W. Blair ll, the President, in the chair, the following Members re elevated to the Fellowship: John Hewitt, Frederick thur Maguire, Donald McIntyre. Wilfred Shaw, and rry Keyte Tenison Collins.

The following were elected Members: Emily Grace th Baillie, *Arthur Capel Herbert Bell, Caroline Anne tt, Elinor Drinkwater Jackson, David Johannes lan. Louisa Martindale, *William George Richards, d *Albert Sharman.

* By examination.

Royal College of Surgeons of England.

At a meeting of the Council on Feb. 11th. with Lord Moynihan, the President. in the chair. diplomas of membership were conferred on 129 candidates. whose names were given in our issues of Feb. 6th and 13th as recipients of the L.R.C.P. (with the exception of G. Ashton. H. F. Bateman, and E. A. Knappett).

Diplomas in public health were granted jointly with the Royal College of Physicians to the candidates whose names appeared in our issue of Feb. 6th.

Sir Percy Sargent was appointed Bradshaw lecturer. and Mr. Francis Weston. F.S.A., past Master of the Barbers' Company, Thomas Vicary lecturer for the ensuing year. Mr. Victor Bonney was reappointed representative of the College on the Central Midwives Board for the period of one year from April 1st, 1932.

The gift of a silver bowl. presented by Sir George Makins, Past President of the College. was reported.

The Chester Royal Infirmary was recognised for the 12 months' surgical practice required of non-members before admission to the Final Fellowship Examination.

The President reported that an election of three Fellows into the Council would take place on Thursday. July 7th next, at 11 A.M. in the vacancies occasioned by the retirement in rotation of Mr. W. McAdam Eccles, Mr. Wilfred Trotter. and Sir Charles Gordon-Watson: that notice of the election would be given to the Fellows by advertisement and by circular on March 11th; and that March 21st would be the last day for the nomination of candidates. and that a voting paper would be sent on April 6th to every Fellow of the College whose address was registered at the College.

Industrial Health Education Society.

The annual meeting of this society will be held at the B.M.A. House. Tavistock-square. W.C., at 4 P.M. on Tuesday. Feb. 23rd. The speakers will be Sir Thomas Horder (the President). Lord Luke. and Sir William Haldane.

Society of Medical Officers of Health.

A meeting of the Fever Group of this society will be held at 1. Upper Montague-street. Russell-square. London. W.C.. on Friday. Feb. 26th. at 4 P.M. A paper will be read by Dr. R. Armstrong on the Serum Treatment of Pneumonia. All interested in the subject are invited to attend.

Society for the Study of Inebriety.

The annual meeting of this society will be held at 11. Chandos-street. London, W.. at 4 P.M.. on Tuesday, April 12th. Dr. J. D. Rolleston will open a discussion on the Cigarette Habit.

Hunterian Society.

Award of the Gold Medal for 1932.—The Examination Committee which met on Jan. 28th was unanimous in awarding the medal to Griffith Ifor Evans. D.M. Oxf., F.R.C.S. Eng., of Caernarvon for an essay entitled "Chronic Familial Syphilis": Gwladys Victoria Smallpiece, M.D., M.R.C.P. Lond.. proxime accessit. The next award of the medal will be made in 1933 for essays received on or before Dec. 31st. 1932. The competition is open to all general practitioners in Great Britain. Ireland, and the Channel Islands. Particulars from the Hon. secretaries. Dr. D. C. Norris. 14. City-road. E.C.1. and Mr. Andrew McAllister, 79, Wimpole-street. W.1.

The *Annual Dinner* of the Society was held on Feb. 11th. at the May Fair Hotel, the President, Dr. David Ross. being in the chair. After the loyal toasts the memory of John Hunter was toasted in silence. Lord Meston. Chancellor of Aberdeen University. proposed "The Hunterian Society," remarking on the revolution in the practice of surgery brought about by Hunter through sheer force of intuitive genius. Dr. Ross in reply. admitted the importance of the Hunterian Society in carrying on the spirit of Hunter. "We are confident," he said. "that we are a great Society," adding. as a good Aberdonian himself. "This is a great night for Aberdeen, with the Chancellor and Rector of its University (Sir Arthur Keith) both present." At the end of his remarks he handed the Society's gold medal designed by Mr. Thornton Shiells. to Dr. Griffith Evans. and circulated a plaque of the medal presented by the honorary treasurer. Dr. Irwin Moore. Sir Thomas Carey Evans proposed "The Lord Mayor and Corporation of the City of London," and Sir Maurice Jenks in reply said how proud the City was of its association with Hunter and the Hunterian Society. Dr. D. A. Coles proposed "The Guests and Kindred Societies" to which Mr. Justice McCardie and Col. C. T. Samman, late Master of the Apothecaries' Society. replied. Sir Arthur Keith added a few graceful words. remarking that. if Hunter himself. "that red-haired and rather quarrelsome man from Scotland," had been present. he might not have been instantly appreciated by the company; but. he added. he was a man who looked deeply into life and his greatness is still being disclosed.

were to be made during the later stages of the Bill to secure the repeal of Section 120 of the 1908 Act which prohibited the admission of children to public house bars. He urged the Government to resist to the utmost any amendment of the law in that direction.

After further debate, the Bill was read a second time.

The financial resolution in connexion with the Bill was agreed to in Committee.

VETERINARY SURGEONS (IRISH FREE STATE AGREEMENT) BILL.

The Veterinary Surgeons (Irish Free State Agreement) Bill, a measure to confirm and give effect to a certain agreement made between His Majesty's Government in the United Kingdom and His Majesty's Government in the Irish Free State with respect to the registration and control of veterinary surgeons, passed through Committee in the House of Lords on Tuesday, Feb. 16th, without amendment.

IMPORT DUTIES BILL.

The second reading of the Import Duties Bill was debated in the House of Commons on Monday, Feb. 15th, and Tuesday, Feb. 16th. The measure applies a 10 per cent. *ad valorem* tariff to imports into this country with the exception of a free list of articles detailed in the first schedule, including wheat in grain, meat—i.e., beef, veal, mutton, lamb, pork, bacon, ham, and edible offals, but not including extracts and essences of meat or meat preserved in any air-tight container—fish of British taking, including shell-fish, tea, newspapers, periodicals, printed books, raw rubber, rubber latex, gutta percha and balata (raw), sulphur, mineral phosphates of lime, and radium compounds and ores.

On the conclusion of the second day's debate the motion for the rejection which had been moved by Mr. LANSBURY on behalf of the Opposition was negatived by 451 votes to 73—majority, 378. The Bill was then read a second time.

HOUSE OF COMMONS.

THURSDAY, FEB. 11TH.

Anthracosis and Silicosis.

Sir WILLIAM JENKINS asked the Home Secretary what progress had been made to get anthracosis scheduled in the workmen's compensation regulations in order to secure payments for men suffering from this disease in the mining industry.—Sir HERBERT SAMUEL replied: It has not been established that work in the anthracite mines is a cause of special pulmonary disease. The question of the effect of coal dust on the lungs has been referred to the Pulmonary Diseases Committee of the Medical Research Council for investigation, and it has been found that there are serious technical difficulties in prosecuting the researches necessary for determining the question. I am informed that it is receiving the close attention of the Medical Research Council, but I am sorry I cannot say when the work is likely to be brought to completion.

Sir WILLIAM JENKINS asked the Home Secretary what number of men had claimed compensation who were suffering from silicosis in South Wales; the number who succeeded in their claim; and the number refused, if any, and upon what grounds.—Sir HERBERT SAMUEL replied: Separate figures for South Wales as not available, but the Returns for Great Britain show that in 1929 there were 12 cases, and in 1930 18 cases of coal-miners who recovered compensation for disablement from silicosis. The Returns for 1931 are only now being collected. I regret that I am not in a position to give the total number of claims made or refused, or the reasons for refusal.

Dust as Factor in Crime Detection.

Mr. ROBINSON asked the Home Secretary whether his attention had been drawn to the scientific investigations made by foreign police experts into the analysis of dust as a factor in crime detection; in particular, whether he was aware of the work of Dr. Edmond Locard, of Lyon; and whether the Metropolitan police had adopted or investigated the methods advocated, and with what results, in any recent crimes.—Sir HERBERT SAMUEL replied: Yes, Sir. The Commissioner has continual and careful watch kept upon all developments in the scientific side of criminal investigation and has had his attention called to the work of Dr Locard and many others. The Metropolitan police employ the best experts in the particular subject whenever it appears that scientific assistance is likely to be helpful. Careful scientific examination of dust is made wherever necessary, and although such cases are rare, the best technical assistance has been obtained whenever there has been grounds for supposing that it was likely to be of value.

Nursery Schools.

Mr. DAGGAR asked the President of the Board of Education how many new nursery schools had been opened and how many plans had been approved from July 1st, 1929, to August, 1931; and how many had been opened and plans for others approved since that date.—Sir DONALD MACLEAN replied: Between the beginning of July, 1929, and the end of August, 1931, 18 nursery schools were recognised for the first time by the Board of Education. In 13 of these cases the plans had been approved during the same period. Since the end of August, 1931, 5 further schools have received recognition, plans in all these cases having been approved before that date and after July, 1929. Plans for 10 further schools were approved between the beginning of July, 1929, and the end of August, 1931, and for one further school since the latter date. Apart from one voluntary proposal which has been abandoned, most of these 11 schools are either already opened though not yet formally recognised, or are approaching completion.

Viscountess ASTOR asked the President of the Board of Education whether he was aware that the Bradford Elementary Education Subcommittee had decided to cut down the milk supply of children in nursery schools to one-third of a pint per day, in spite of the fact that over 50 per cent. of the children in the Bradford Nursery School were on the free lists, which meant a poverty basis and very little milk supplied in their homes; and whether he would issue a circular to all education committees giving the opinion of the Medical Research Council on the subject and requiring the issue of the correct quantity of milk to all children.—Sir DONALD MACLEAN replied: I have no official information as to any changes made by the Bradford Local Education Authority in the matter of the supply of milk to children in their nursery schools, but I have seen a statement in the press that certain modifications had been made on an experimental basis to be reconsidered next April. The Board's regulations in regard to nursery schools require that adequate arrangements must be made for attending to the nourishment o the children, and I am staisfied that this requirement i being generally met, not only by the provision of milk but normally by the supply of good dinners also, and I d not therefore think that it is necessary to issue a circula to local education authorities on the subject.

Staffing of Oldchurch Hospital.

Mr. HUTCHISON asked the Minister of Health whethe he could investigate the staffing of the Oldchurch Hospita at Romford, where recently an attendant lost his life i the execution of his duty by being attacked by an insan patient; whether the staff was adequate for the purpose; and whether he was aware of the dissatisfaction of the staff with the conditions of working and with the obsolete character of the buiding.—Sir E. HILTON YOUNG replied: Yes, Sir. I have asked for a report upon these matters. Pending the receipt of that report my hon. friend will, I am sure, not expect me to express any opinion in regard to the subject matter of the second part of the question.

Imports of Liquid Milk.

Brigadier-General CLIFTON BROWN asked the Minister of Health who were the principal importers of liquid milk during the last three months who were registered by the port sanitary authorities of London, Harwich, and Newhaven; and whether any of the liquid milk imports came in pasteurised.—Sir E. HILTON YOUNG replied: It is compulsory for importers of liquid milk to be registered with the Local Authority under the Public Health (Imported Milk) Regulations, and I do not think that I could properly give a list of the names of persons thus required to be registered. With regard to the last part of the question, there is reason to believe that most, if not all, the imported milk in question is heat treated before shipment.

The Spahlinger Treatment.

Mr. HAMMERSLEY asked the Minister of Health what reports he had received from his officials on the publication by Spahlinger of his formula for the treatment of tuberculosis.—Sir E. HILTON YOUNG replied: I have received from M. Spahlinger a copy of his statement as issued to the press, and I am considering it. I have also sent copies of the statement to the Medical Research Council and other competent research bodies for their observations.

Demonstration in Surgery. 2 P.M., Operations, Medical Surgical, Throat Out patients.

WEDNESDAY.—10 A.M., Medical Wards, Children's Medical Out-patients. 2 P.M., Gynæcological Operations, Medical, Surgical, and Eye-Out-patients. 4.45 P.M., Venereal Diseases.

Royal Free Hospital, Gray's Inn-road, W.C.—Asst. Surgeon to Ear, Nose and Throat Dept.

Royal National Orthopædic Hospital, 234, Gt. Portland-street, W. H.S. At rate of £150. Hon. Dental Surgeon. Also 2 H.S.'s for Country Branch, Brockley Hill, Stanmore. Each at rate of £150.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Hon. Med. Reg.

Samaritan Free Hospital for Women, Marylebone-road, N.W.—H.S. At rate of £100.

(*Continued at foot of next page.*)

The Eugenics Society: the Galton Lecture.

The annual dinner of the Eugenics Society was held at the Rembrandt Hotel, London, on Feb. 16th, the President, Sir Bernard Mallet, being in the chair.

After the dinner the Galton lecture was delivered by Mr. E. J. Lidbetter on the "Social Problem Group"; it was a report upon a detailed and painstaking investigation into the incidence of social inadequacy in an East London district. The main message was the necessity to recognise the existence of a definite race, usually of chronic paupers, breeding-in through successive generations, becoming parasitic upon the community, and passing their lives at the public expense in institutions, asylums, infirmaries, and jails. In illustration of his statements, the lecturer summarised a series of pedigrees which, he said, were in no sense selected but were, on the contrary, representative of hundreds which had been put together; and by the help of diagrams he proved the tendency of these unfortunates to in-breed with great fertility and to produce offspring from generation to generation of insane, mentally and physically defective, and incompetent persons. He pointed to the fact that while the definitely defective, who formed the smaller proportion, could be dealt with in various manners, the higher grade defective, being a freer agent, hampered the whole administrative machinery of society, lowering the general standard of life and of employable labour, and spreading venereal disease. The conclusions reached by the Eugenics Society were, he said, being confirmed by a Departmental Committee from the statistical angle, and the existence of a "Social Problem Group" was being definitely proved. But further and more extensive investigations would have to be carried out before any general remedial measures could be suggested.

A vote of thanks to the lecturer was proposed by the Rev. J. C. Pringle, secretary of the Charity Organisation Society, and seconded by Lord Riddell, who hoped that Mr. Lidbetter would be converted to the view that in voluntary sterilisation a partial remedy, at least, would be found for some of the terrible circumstances revealed. A vote of thanks having been enthusiastically given, Mr. Lidbetter disclaimed any definite opposition to the proposed legislation in respect of sterilisation, but pointed out that in the pedigrees which he had detailed there occurred among the offspring of the "Social Problem Group" a certain proportion of apparently normal persons whose children often reverted to defective types.

The dinner was very amply attended.

Manchester Royal Infirmary.

Weekly post-graduate lectures and demonstrations will be resumed at this hospital on Tuesday next at 4.15 P.M., and weekly demonstrations of clinical cases and methods in wards and special departments on Friday at the same hour. Particulars will be found in our Medical Diary each week.

An Old Patients Association.

Attached to Salford Royal Hospital is an old patients' association, numbering some 1500 members. The fundamental obligation is to subscribe half a crown annually for the maintenance of "grateful remembrance beds." In the last five years three such beds have been opened, and it is expected that a fourth will be produced in the coming summer.

Dr. Jessie Macgregor Prize, Edinburgh.

An award of this prize will be made in July for original work in medicine. Such work must not have been published more than three years previously. The prize is of the value of £70 and applicants must be medical women who have studied at Edinburgh for at least a year and are graduates of the University or hold the triple qualification. The successful applicant is expected to deliver a lecture on her work. Applications marked "Dr. Jessie Macgregor Prize in Medical Science" must reach the convener of trustees, Royal College of Physicians of Edinburgh, not later than April 30th.

Appointments

Overend, H. F., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Acts for Blackpool.

Tivy, C. B. F., M.Ch. R.U.I., a Medical Referee under the Workmen's Compensation Act (Ophthalmic cases) for Circuit 59 and certain districts in Circuit 57.

Whitelaw, A. D., M.D., Ch.B. Camb., Medical Officer of Health, East Herts Combined District.

West Kent General Hospital: Oliver C. Pye, junr., M.B., B.Chir. Camb., Hon. Asst. Physician; Johnston, D. M., M.D. Durh., Hon. M.O. in charge of Artificial Sunlight Dept.

NOTES, COMMENTS, AND ABSTRACTS

GENERALISED SCLERODERMA IN CHILDREN.

Dr. E. Lawrence Oliver,[1] of Boston, has lately described three cases of this rare condition with a review of others. The rarity of generalised scleroderma in children is illustrated, he says, by the fact that of 508 cases collected by Lewis and Heller in 1895, only 10 were met with under 15 years of age, while of 103 cases of scleroderma, of which 48 were generalised, reported by O'Leary and Nomland in 1930, none occurred in children. The principal cause alleged to account for the condition is hypofunction, hyperfunction, or dysfunction of one or more of the ductless glands, especially the thyroid or suprarenals. It is noteworthy in this connexion that among 111 cases of dermatoses associated with exophthalmic goitre Hyde and McEwen found five examples of scleroderma. As regards the immediate possible causes of generalised scleroderma almost every common infection has been incriminated, especially rheumatic fever, the other infections regarded as responsible for some cases being influenza, syphilis, diphtheria, erysipelas, and tonsillitis. Oliver, however, thinks it most probable that these infections act merely as the spark that starts the conflagration and that other factors must be present to supply the inflammable material. He agrees with Hoffmann and Michael in the belief that an unstable vegetative constitution is the fundamental cause. The prognosis of generalised scleroderma in children is evidently much brighter than in adults. for most of the recorded cases have recovered. Of Oliver's three cases complete recovery took place in two and considerable improvement in the third. While it is doubtful if there is any specific treatment for the condition, a trial should be made of thyroid extract or extracts of other endocrine glands. The patients should be guarded against the cold to which they are supersensitive, and in most cases they will derive benefit from massage, which aids the circulation and prevents loss of mobility.

LIVING IN TWO WORLDS.

In "The Great Amphibium,"[2] Dr. Joseph Needham prints four lectures on the position of religion in a world dominated by science. "Thus is man," said Sir Thomas Browne, "that great and true Amphibium whose nature is disposed to live, not only like other creatures in diverse elements, but in divided and distinguished worlds." Dr. Needham agrees, and he sees a clear division and very little prospect of reconciliation between man's attempts to apprehend the world's ultimate mystery, which we call religion, and his efforts to investigate the world's apparent mechanism, which we call science. Valuing both as integral parts of human nature, he is content to leave them at variance and in opposition to one another. We commend his arguments to anyone who is interested in such questions, but we cannot help feeling that he has misled himself by attributing to science and the scientific outlook qualities which are flatly contrary to experience and represent a crude and elementary view of the situation, which does not actually exist. He says, for instance, that the incomprehensibility of God is the basis of religious mysticism, while the comprehensibility of the universe is the corner-stone of science; in actua experience, the religious and scientific interests of a human being are based on just the same ideal—th hope that by paying attention to the matter we ma *some day understand something* which at presen seems mysterious. He lives all the time in the sam world, and we judge that Dr. Needham has constructe an entirely unreal abstraction in putting together scientific atmosphere in which ethics and reveren have no place.

HIGGINSON'S SYRINGE.

EVERYONE knows Higginson's syringe, but few a aware that its *hero eponymus* was a surgeon on t staff of the Liverpool Southern Hospital in t 'seventies, with bushy eyebrows, a long white bea and a strong resemblance to Charles Darwin. T was told to the Section of the History of Medic of the Royal Society of Medicine on Feb. 3rd Dr. Dan McKenzie, who also showed a picture o bulbous rubber enema syringe, made and used savage natives of Brazil, where rubber grows w He observed that the ancient Egyptians and oth in antiquity used enemata, administered by a syrin a funnel, or a long cylinder, the patients in the pr or knee-elbow positions, as in pictures exhibit A social fashion of giving enemata arose in the co of Louis XIV., which explained the references Molière (1660), but it did not spread extensivel England. Brass enema pumps with india-ru tubes were shown, permitting administration in sitting or supine positions, and allowing administration. The advance of rubber ma facture made Dr. Higginson's proposal practica It may be added that the frequent giving of enem on board ships—so often referred to by Smollett a 1740—must have been especially difficult, as th then were. Incidentally, as is well known, it was surgeon Syme who first devised the method, introduced to industry by Mackintosh, of w proofing cloth with a solution of india-rubber.

A WARNING.

Mr. Hamilton Kirk, M.R.C.V.S., writes 658, Finchley-road, London, N.W. 11.

"I wish to give timely warning to all practitio not to purchase a second-hand Philips Me Portable X ray apparatus bearing the maker's nu 4760, or (more significant still) no number at This set, in a leather case and with an auto-t former No. 138284, was stolen from my moto and I have offered £15 reward to anyone who help me to recover it."

ADDRESSES AND ORIGINAL ARTICLES

SOME FACTORS IN THE CAUSATION OF HYDRONEPHROSIS.*

BY J. P. HOSFORD, M.S LOND., F.R.C.S. ENG.,

FIRST ASSISTANT IN THE SURGICAL PROFESSORIAL UNIT, ST. BARTHOLOMEW'S HOSPITAL.

THE causes of hydronephrosis may be divided into congenital and acquired. The term *congenital hydronephrosis* at once raises a difficulty in nomenclature, because there is a type commonly called congenital in which the dilatation affects mainly the pelvis of the kidney. In that the dilatation is probably not present at birth it is not really congenital, although the factors (whatever they be) which cause it may be congenital. It is best to confine the term congenital to those types of hydronephrosis which are present in the new-born or are discovered soon after birth. It is found that they fall into two main groups :—

(1) Where there is some discoverable mechanical cause obstructing either the ureter or urethra.

(2) Cases of megalo-ureter combined with hydronephrosis in which there is no discoverable obstruction.

In the first group the ureter may show a definite stricture, narrowing, or fold, or it may present as an impervious cord. In quite a number of those cases showing distension of the bladder, as well as distension of the ureters and kidneys, some congenital mechanical obstruction [1] can be found in the posterior urethra. The commonest is a valve,[2,3] so arranged that it obstructs the downward passage of urine, but does not prevent the upward passage of a bougie.

In the second group, where no obstruction can be found, the ureteric orifices and bladder sometimes share in the dilatation, though in others the kidney and ureter of one side are alone affected. The cause of the dilatation is unknown, but it has been suggested by some authorities that the explanation may be an embryological one. It has been shown by Gerard [4] that the ureters in fœtal life up to the third or fourth month are of large calibre, as compared with the size of the kidney and the rest of the body. Deficient development of the musculature of the ureter may be the cause.

This musculature does not begin to develop until the third month—it begins at the lower end of the ureter and gradually spreads up to the renal pelvis. Eisenstaedt [4] says that an imperfect development, a true hypoplasia of the muscle-fibres must be seriously considered as a possible cause. This possibility, in addition to the persistence of the wide calibre of the ureters as seen in early fœtal life, may explain the condition of congenital megalo-ureters and dilatation of the renal pelvis.

I wish to divide the causes of *acquired hydronephrosis* into two groups also :—

(1) When there is a demonstrable macroscopic obstruction.

(2) When there is no such obstruction.

In the first group the obstruction may be due to a variety of lesions, amongst which may be mentioned calculus, neoplasms or tuberculous inflammation obstructing the ureter, ureteral strictures, and ureteral kinks. In connexion with the last of these I will refer later to aberrant vessels and abnormal mobility of the kidney. I do not propose to deal with the question of urethral or bladder obstructions in the cause of hydronephrosis.

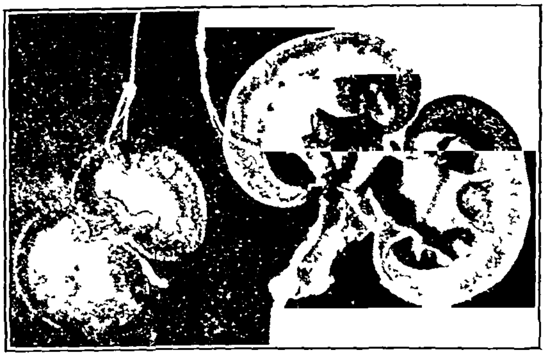
The group of cases where there is no demonstrable macroscopic obstruction is of much greater interest, and I will refer to it at some length later on.

Effect of Obstruction of Ureter.

I now wish to consider the effect on the kidney of obstructing the ureter. Information on this subject can be derived from animal experiments and from human pathological material and from those uncommon occasions when the ureter in man, or more commonly woman, is tied intentionally, or by accident, in the course of some surgical operation.

It is often taught and it is still stated in many text-books that a ligature tied tightly around a ureter so as completely to obstruct it does not cause a hydronephrosis, but brings about an anuria and primary atrophy of the kidney. Now this is contrary to nearly all experimental evidence. It has repeatedly been shown that complete obstruction to a ureter in different animals causes a hydronephrosis. Working with rabbits I have found that in every case where the ureter has been completely obstructed, whether it be at the upper or lower end or in its middle, a hydronephrosis has developed, and in no instance has there been a primary atrophy. There can have been no question about the completeness of the obstruction, because the ureter was doubly ligatured and divided between. The only way in which I have produced a primary atrophy experimentally when the ureter has been obstructed, is by performing a simultaneous ligature of the renal artery.

FIG. 1.



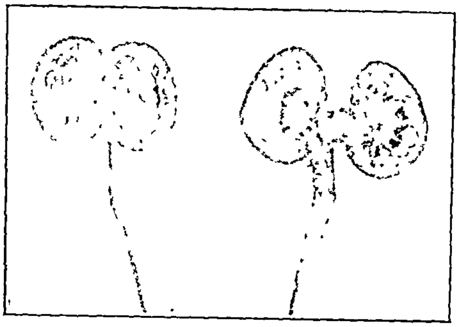
Hydronephrosis of left kidney of rabbit produced by complete ligature of ureter. Animal killed after 14 days.

As the hydronephrosis increases in size there is a gradual destruction or atrophy of the renal parenchyma, and eventually the condition of hydronephrotic atrophy results in which all the renal secreting tissue is destroyed, and a thin-walled sac of watery fluid remains. The larger the animal the longer does it take for complete hydronephrotic atrophy to become established ; the time for this to happen in man is unknown, but in the rat it is about four months, in the rabbit ten months, and in the dog 18 months or more. In experimental work a primary atrophy has occasionally been produced, but only in cases with an associated pyelonephritis. It is well known that a hydronephrosis of considerable size can form without causing any symptoms, and it is probable that when a ureter is ligatured in man a hydronephrosis follows, and goes on to the stage of hydronephrotic atrophy without causing symptoms. There is little clinical material from which to gain information on this point, but A. E. Belt,[5] in reviewing 64 cases of complete ureteral ligature collected from the literature, found that in 38 there was definite evidence of renal disturbance, either immediate or at some later time. Out of 17 of these cases, in which a later examination was obtained, it was found that 14 showed a definite hydronephrosis.

---

* Hunterian lecture delivered before the Royal College of Surgeons of England on Feb. 1st.

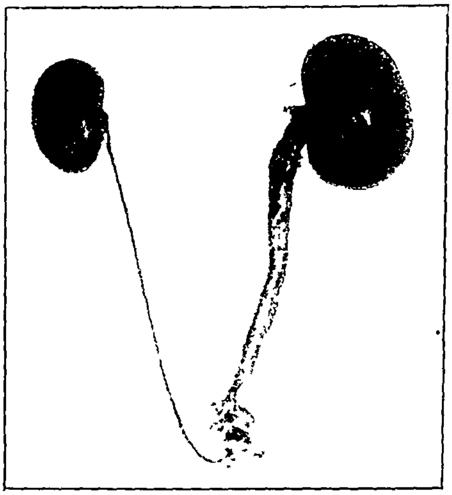
FIG. 2.



Hydronephrosis of left kidney of rabbit produced by incomplete ligature of ureter. Animal killed after 11 days.

An incomplete or partial obstruction to a ureter, as is well known, produces a hydronephrosis. The rate of formation and eventual size of the hydronephrosis varies, of course, according to the degree of obstruction. The types of hydronephrosis which are found experimentally with complete and partial ureteral obstruction are the same—they differ only in degree. The rate of formation is more rapid with a complete obstruction, though with an incomplete obstruction the hydronephrosis will progress to a much greater size, but eventually in most cases there will be a total atrophy of the renal parenchyma. Another question which is asked is whether there is any difference in the hydronephrosis produced by a high or low ureteral ligature. Answering from experimental work in animals it can be said that the type of hydronephrosis as regards proportional dilatation of pelvis and calices is the same, but the size of the hydronephrosis is usually a little different; with a low ureteral ligature the rate of formation is somewhat slower than with a high ligature. This has been my experience also.

FIG. 3.



Hydronephrosis and hydroureter of left kidney of rabbit produced by complete ligature of ureter at lower end. Animal killed after 14 days.

Functional Obstruction.

So far I have referred to anatomical obstructions to the ureter. Can there be such a thing as physiological or functional obstruction causing hydronephrosis? The urine secreted by the kidney is conveyed along by a wave of peristalsis. This wave starts in the major calices near the tips of the renal papillæ and sweeps over the pelvis; it slows up at the pelvi-ureteric junction, and then becomes more marked as it passes along the ureter. Stimulatic
by pinching only sets up a wave of contraction wh
the stimulus is applied to the area near the tips
the renal papillæ—other areas are refractory. Stim
lation of the ureter causes much stronger contractio
than can be obtained in the pelvis. Now it mig
be thought that if this peristaltic wave in the calic
pelvis, and ureter were interrupted, there might be a paralytic obstruction to the outflow of urine such as is known to occur in the intestine in paralytic conditions. Experiments were done in an attempt to produce such an obstruction. The ureter in a rabbit was exposed transperitoneally, the periton
being divided over its whole length. It was then li
free from the posterior abdominal wall, the l
areolar tissue being stripped from it so that
ureter remained attached at only its two ends.
apparently in no way interfered with the no
peristalsis, because after 21 days the kidney sho
not even the earliest degree of hydronephrosis.

FIG. 4.

Watson Beach,[6] in an in
gation into atony of the u
as a cause of hydronephrosis, removed
2 cm. of the ureter in a rabbit and rep
it by a glass cannula. He found some dilat
of the ureter above the cannula, and a

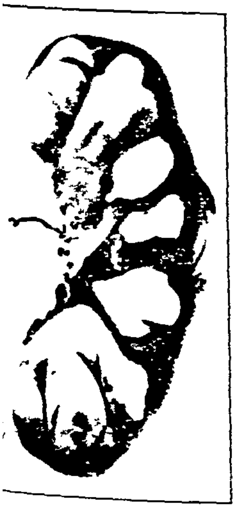
degree of hydronephrosis. A rabbit's ureter is very small, and to insert a cannula into it in such a way as to cause no fibrosis or mechanical obstruction cannot be at all easy. It is difficult to assess the exact value of his experiments as demonstrating a functional obstruction, because there is such a considerable likelihood of producing some fibrosis and mechanical block where the cannula is inserted, and also because the experiments of stripping off all the muscular coats of the ureter give results opposed to Beach's.

Types of Hydronephrosis.

Before proceeding further with the causes it may be well to mention the different types of hydronephrosis. The following will be discussed: (1) renal type; (2) pelvi-renal type; (3) pelvic type.

It is not always easy to separate these three sharply from one another, but in the *renal type*, which is usually due to a calculus, the kidney is considerably enlarged owing to a dilatation of the calices and destruction of the renal parenchyma, the pelvis being scarcely increased in size at all, or only sufficiently to contain the calculus or calculi.

FIG. 5.



Renal type of hydronephrosis with calculus in pelvis, removed at operation.

The *pelvi-renal type* is usually due to some definite visible obstruction to the ureter below the pelvi-ureteric junction—it may be within the lumen of the ureter, in its wall, or from external pressure.

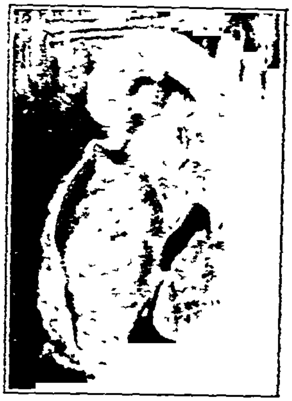
In the *pelvic type*, although the whole kidney shares in the dilatation, the pelvis is mainly affected. It is often spoken of as the congenital type; this is probably an incorrect term, because it is unlikely that it is present at birth, although the factors which cause it may be some congenital defects or maldevelopments. Idiopathic is a better term, although it takes us no nearer the cause. The origin of this type of hydronephrosis is usually obscure. Many papers have been written on this subject.[7, 8] Most of them are devoted mainly to explaining why the obstruction, which is at first not evident, really exists; and, in an endeavour to understand the cause, too little attention seems to be paid to the really rather remarkable fact of the disproportionate dilatation of the pelvis as compared with the remainder of the kidney.

Causes of "Idiopathic" Hydronephrosis.

I think it well to examine for a few minutes some of the causes which have been or are put forward to explain the occurrence of this so-called idiopathic type of hydronephrosis.

(1) *Stricture of the ureter.*—There is a great difference of opinion amongst urologists as to the frequency of occurrence of ureteral stricture. In 1925 Hunner was quoted as having seen over 2000 cases, while other urologists of wide experience meet with them but seldom. In many of the cases of idiopathic hydronephrosis a stricture is described as being present at the pelvi-ureteric junction, and on examining specimens of this condition a narrowing certainly is sometimes found. It is, however, uncommon to find that during life a full-sized ureteric catheter cannot easily be passed right up into the renal pelvis, so that no very marked narrowing can be present. Hunner believes that focal sepsis is much the commonest cause of ureteral strictures. Winsbury White, who has done much work on this subject, believes that the earliest cases show narrowing of the ureter from chronic inflammation, and that this appears to be the cause of the dilatation. But why, one asks, does the dilatation affect mainly the pelvis.

FIG. 6.



Pelvic type of hydronephrosis.

(2) *Abnormal mobility of the kidney* has frequently been blamed as a cause of hydronephrosis. It is suggested that the unusually low descent of the kidney causes a kinking of the ureter, but it is difficult to see why or over what it becomes kinked. Apart from aberrant vessels there are no structures commonly present which can be found post mortem, or at operation, which might cause such a kink. It is true that by pyelography, either by means of a ureteric catheter or by excretion methods, kinks can be demonstrated in patients who have attacks of renal pain; but frequently there is no associated hydronephrosis. Movable kidney most commonly causes symptoms in the fourth or fifth decade, while idiopathic hydronephrosis is usually seen before this. Many cases of movable kidney of long standing, although having attacks of pain, show no real evidence of hydronephrosis, although the symptoms may be relieved by nephropexy. This operation not uncommonly brings definite relief of the pain, but it is no proof that it is due to relieving a hydronephrosis by straightening out the ureter. Unless the kink is very sharp the ureter is a structure unlikely to be obstructed, because being a muscular tube it can straighten itself out somewhat in parts as waves of peristalsis pass along it. It is true that a sharp kink will cause a hydronephrosis by obstructing the ureter. I have shown this experimentally by kinking the ureter in a rabbit by means of a piece of silk which was attached to the muscles of the posterior abdominal wall above the kidney, and below was looped round the ureter about 1 cm. from the pelvi-ureteric junction. A well-marked hydronephrosis had formed in 28 days. The experiment was repeated, but this time the silk thread was attached above to the twelfth rib. In both cases there was a hydronephrosis and dilatation of the ureter on the proximal side of the distorting silk.

(3) *Aberrant renal vessels* are very frequently mentioned as a cause of hydronephrosis; but I think that probably the majority of urologists now agree that the pressure of the so-called aberrant vessel on the pelvi-ureteric region is usually a secondary affair; by that I mean that the artery does not press upon and kink the ureter or renal pelvis while they are of normal size, but that it is only when dilatation of the pelvis from some other cause has occurred

that this pressure and kinking effect occurs. Very frequently the artery which is called aberrant is really only the inferior branch of the renal artery entering the lowest part of the hilum of the kidney. The term aberrant should be reserved for those cases where there is an artery which, arising from either the main renal artery or the aorta, enters the lower pole of the kidney not by way of the hilum but actually through the renal parenchyma.

Winsbury White has described very clearly the mechanism by which the renal pelvis becomes involved by the inferior renal artery. He found in 9 out of 11 examples that the vessel implicating the ureter is a normal inferior branch of one of the main renal vessels. This branch runs down across the front of the pelvis to enter the lower part of the hilum, while the main renal artery lies above and behind the pelvis so that the latter lies between two arteries. As the pelvis enlarges for any reason it tends to bulge forwards between these two arteries owing to less resistance in front, and as it does so it hangs over and is constricted by the inferior artery lying in front. In a number of the cases of hydronephrosis associated with what at first appears to be an obstructing artery, it is found on closer examination that the constriction is not exactly at the point where the artery crosses the ureter; sometimes it is above, and rarely below.

(4) *Folds and valves.*—It is not an uncommon experience in cases of hydronephrosis of the pelvic type to find what is taken to be a valve or fold at the pelvi-ureteric junction. This valve is probably secondary to the dilatation, and not the primary obstruction causing it. As the pelvis gradually dilates in many cases of hydronephrosis it may be noticed that the dilatation occurs most markedly in the lowest part of the pelvis—this is like the urinary bladder enlarging in obstructive cases, for here, as in the pelvis, it is the lowest part or base which first enlarges most rapidly. This unequal enlargement has two effects: firstly, it causes the condition of high implantation of the ureter in the pelvis, because the relative distances from the ureter to the upper and lower borders of the hilum are altered. This high implantation is probably rarely, if ever, congenital. Secondly, it causes a valve-like opening, and this is exaggerated as the upper end of the ureter becomes adherent to the pelvis. This valve-like opening, once it is established, of course acts as an obstruction to the outflow of urine, and so causes the hydronephrosis to progress further; but it is almost certainly secondary to the dilatation and is neither a congenital malformation nor an initial cause of the hydronephrosis.

UNEXPLAINED CASES.

Although all the mechanisms mentioned above are possible causes of hydronephrosis, there are many cases in which it is difficult to say what primarily caused the condition. In some, several lesions which might account for it are found, while in others none at all can be discovered; but even in those cases where one or more lesions may be found, these are often secondary to the hydronephrosis and not the primary condition producing it. All these causes are mechanical and not functional. Often no visible obstruction is found. Indeed, as has already been mentioned, in the majority of cases a ureteric catheter can be passed right up into the renal pelvis, and in some the pelvi-ureteric junction has been described as being larger than usual, and although the hydronephrosis may reach a tremendous size it does not seem to be able to empty. In this connexion it may be *interesting* to recall the account of what is probabl the largest hydronephrosis ever recorded.

> In 1746 Dr. Glass [9] gave a most careful and convincin account of a post-mortem examination on a young woma of 23 who had had a large belly *for many* years. Tl circumference of the abdomen was six feet four inche When the abdomen was opened, he tapped the huge flu swelling and describes how he "evacuated a surprisi quantity of water, which was lightly tinged of a coff colour, limpid *as urine, and not in the least fœtid.* Tl water was carefully measured and found to be not above pint less than 30 gallons wine measure; which must weig according to common calculation, 240 lbs."

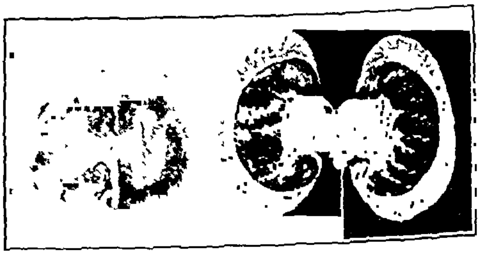
In describing the kidney and ureter Dr. Glass sai on the left inferior part was discovered the orifi of a duct, which opened obliquely into the cavi of the saccus, and would easily admit of a large goo quill. The oblique opening he mentions was probab the condition of oblique valve-like opening to whi I have already referred and which is secondary the dilatation of the kidney. We must therefore lo for some other cause for these hydronephroses.

Two questions have to be answered—what is t nature of the obstruction, is it mechanical functional? and secondly, though of equal importan why does the pelvis show a distension out of proporti to the remainder of the kidney? Can any help obtained from experimental work on animal Such work has already been briefly referred to, l it may be said at once that I can find no account any worker having produced what may be considered example of the pelvic type of hydronephrosis, inde the type of hydronephrosis is not referred to exc in a few papers, although there is a fairly abund literature on experimental hydronephrosis.[5 10–12]

EXPERIMENTS.

Working with rabbits I have been unable to prod a lesion of the kidney which could be considered be an example of a pelvic type of hydronephro

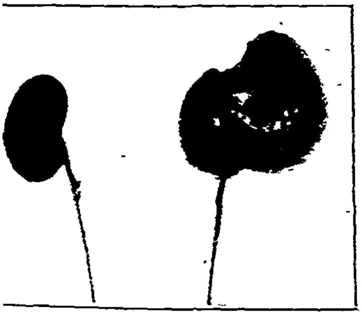
FIG. 7.



Hydronephrosis of left kidney of rabbit produced by comp ligature of ureter. Animal killed after 91 days.

although it is perfectly easy to produce a hy nephrosis in these animals, and I have done so i variety of ways. The ureter has been comple occluded by ligature and division in different anir for periods of one week, two weeks, six weeks, 13 weeks; the ureter has been partly occlu for two weeks in one animal and for seven we in three animals. This partial occlusion has b carried out in the majority of cases by tying a ligature around the ureter so as to obstruct it aln completely; an encircling fine silver band has been used to cause a partial obstruction. Both complete and partial ligatures have been app at the pelvi-ureteric junction and at the blad end of the ureter as well as in the middle portio its course. The ureter has been kinked immedia below the pelvi-ureteric junction by a silk thr ich was not tied around it but merely dragged it nly out of its course. The kidney and ureter its entire length have been lifted from their bed d all the connective tissue stripped off them so it probably the nerve-supply to the ureter except h fibres as may come along the renal artery and n was destroyed. The muscular coats of the eter for some distance have been stripped off, leaving only the mucous membrane. The renal vein has been ligatured at the same time as the ureter. The renal artery has been ligatured at the same time as the ureter. On different animals the anterior and posterior divisions of the renal artery have en ligatured at the same time as the ureter. Rabbits re used in all these experiments and the left kidney d ureter in nearly every instance. In not a single periment was a hydronephrosis of the pelvic type oduced. In every case the hydronephrosis was ally of the pelvi-renal type, except when the ature was so high up as to prevent the pelvis from lating. In one group of experiments, however, condition which at first sight resembles somewhat pelvic type of hydronephrosis was produced (Fig. 8). o obtain this the operation performed consisted of posing the kidney through a lumbar incision, fining the renal artery as it lies above and behind e renal vein and following it until it divides into s two terminal branches, anterior and posterior, st before they enter the hilum. The posterior ivision which in rabbits, as in man, is the smaller f the two, though in the majority of animals it is e larger, is ligatured with fine silk; the ureter is en ligatured tightly. There is no inter-communication between the areas of the kidney supplied by the terior and posterior divisions of the renal artery, nd so the area supplied by the branch which is atured becomes an anæmic infarct. The result is at with the ureter tied and therefore the pressure ightly increased, the infarcted posterior area dilates ery much more rapidly than the anterior part which ill has its normal blood-supply. The result is eally a diverticulum of the posterior half of an rdinary hydronephrosis.

FIG. 8.



ydronephrosis; giving appearance of pelvic type hydronephrosis. Produced by ligaturing ureter and the posterior division of renal artery. Animal killed after 14 days.

The Pelvi-ureteric Junction.

I now wish to return to a consideration of the problem—Can there be a functional obstruction at he pelvi-ureteric junction in the absence of an rganic one, and if so, can this in any way be associated with the unusual dilatation of the pelvis which occurs in the pelvic type of hydronephrosis? The question of spasm at the pelvi-ureteric junction at once suggests itself, but is there a sphincter here?

In some detailed descriptions of the anatomy of the renal pelvis a ring muscle or sphincter is figured at the pelvi-ureteric junction. Ring muscles at the junction between major calices and pelvis as well as at the pelvi-ureteric junction and other places were beautifully demonstrated by Max Brödel[13] over twenty years ago. These ring muscles are not well-defined structures like the pylorus, and, indeed, many anatomists deny the presence of an anatomical sphincter at the pelvi-ureteric junction, while others do admit that there is a slight thickening of the circular muscle-fibres at the pelvi-ureteric junction and at other narrowings in the ureter. Though there may be no anatomical sphincter, this does not exclude the possibility that there may be a functional or physiological one. The presence of some such sphincter is suggested by the observations of Dardinski[14] while observing peristalsis in human renal pelves and ureters. The wave of peristalsis, as it sweeps over the entire pelvis, slows up as it reaches the pelvi-ureteric junction to become more vigorous again as it arrives at the ureter. This suggests that the neuromuscular mechanism is not quite a continuous one. The presence of this sphincter has been demonstrated experimentally in animals by Pannett,[15] by gradually dilating the ureter with fluid run into it through a fine cannula from below. The ureter dilated from below upwards from the point at which the fluid was run in, up to the pelvi-ureteric junction; here the dilatation ceased, the pelvis presumably being protected by a sphincter at the pelvi-ureteric junction. It might be thought that the renal pelvis would have a thicker wall than the ureter, and that this might account for its failure to dilate; actually the converse is true, the renal pelvis having a somewhat thinner wall than the ureter.

If there were a spasm at the pelvi-ureteric junction causing the hydronephrosis, and considering the length of time that this would have to continue, one would expect to find hypertrophy of the circular muscle at this point, but this is not found. Also, so simple an obstruction as a spasm would not be likely to cause the peculiar dilatation of the pelvis, any more than a dilatation of pelvis and kidney. Another suggested explanation is that there is some disorder of the neuromuscular mechanism of the pelvis so that the peristalsis of the calices and pelvis is disturbed, and the urine not being conveyed away gradually accumulates in the pelvis, which therefore dilates. If the peristalsis in the ureter continued to work normally, while the peristalsis in the pelvis was irregular or weak, the abrupt demarcation between pelvis and ureter which is seen in many cases could be accounted for.

Can it be that there is a congenital deficiency in the formation of the muscle of the pelvis so that it dilates more readily than the remaining portion of the kidney? This point cannot be proved, but the facts are against it, because in a certain number of the cases a very well-marked and strong peristalsis can be seen continuing in the pelvis after nephrectomy; also, microscopically, the muscle in the pelvis is seen to be well developed, and in some cases increased in amount. It is true that in specimens of an advanced degree of this type of hydronephrosis the pelvic wall is very thin, but this is due to the great dilatation.

Achalasia of the Sphincter.

The pathological explanation which appears best to cover this condition of pelvic hydronephrosis, where no primary obstruction is apparent, and even possibly some of those cases where some obstruction is present, is achalasia or lack of relaxation. This condition occurs in various parts of the body, notably the cardiac orifice of the stomach, and the colon in Hirschsprung's disease. The condition of achalasia of the cardia,[16 17] which is now, I think, a well-established entity, has been studied extensively by many workers. I will give a brief account of it in order to be able to compare the condition of idiopathic pelvic hydronephrosis with it.

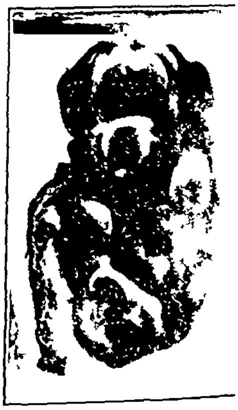
On examining specimens of the lower part of the œsophagus and cardiac end of the stomach, no well-marked sphincter can be demonstrated macroscopically, there is nothing at all comparable with the pyloric sphincter; but it is nevertheless generally agreed, and there can be no doubt of the fact, that there is a functional sphincter if not an anatomical one. It can be seen with an œsophagoscope. In a healthy person the cardia does not make itself known to us. so that we may forget its presence even during the act of swallowing. In cases of achalasia of the cardia, it is found at post-mortem examination that there is no appreciable hypertrophy of the circular muscle at the cardia, the cardia is in fact open, and water can be poured through it, there being no apparent obstruction. There is, however, the established fact of difficulty in emptying the œsophagus, and food accumulates on the proximal side of the cardia. At first there is an hypertrophy of the œsophagus above the cardia. Later this gives way to an atrophy and great dilatation. This dilatation of the œsophagus is an outstanding feature in cases of achalasia of the cardia.

Now to compare these facts about this condition with the idiopathic type of hydronephrosis, let us first consider the sphincter. As I have already said, there is a functional sphincter at the pelvi-ureteric junction, even if there is not an anatomical one; but in either case it is fairly comparable with the cardia, and in neither instance is there a well-developed powerful sphincter such as occurs at the pylorus. The natural action of the pylorus throughout a part of digestion is to prevent food passing in spite of peristalsis trying to force it through, whereas the cardia and pelvi-ureteric sphincter allow the easy passage of food and urine respectively.

In cases of hydronephrosis without apparent obstruction there is, as in cases of achalasia of the cardia, no hypertrophy of muscle found at the pelvi-ureteric junction. A further similarity between the two conditions may be noted in regard to the muscle of the renal pelvis. In the early stages of hydronephrosis there is hypertrophy of the muscle; in two cases of this condition where nephrectomy had been performed, very powerful deep peristaltic waves were seen to continue for upwards of half an hour after the kidney had been removed from the body; the pelvic wall was thickened in each case. Winsbury White,[18] in describing an early case of hydronephrosis, says a considerable degree of muscular hypertrophy can be made out; and Hinman,[5] who has done so much work on hydronephrosis, describes hypertrophy of the muscle about the pelvis as being often most pronounced and extending well up on to the major and minor calices. In the later cases hypertrophy gives way to atrophy, and a considerable degree of dilatation occurs. As already mentioned, in achalasia of the cardia there is first an hypertrophy of muscle in the œsophagus, followed by atrophy and dilatation.

One authority, to whom I have already referred, has said that the inflammatory changes in the pelvis and ureter can quite easily explain all the changes which occur in hydronephrosis from the inception of the disease to its termination. Undoubtedly a stricture at the pelvi-ureteric junction due to chronic inflammation or to any other cause will bring about a hydronephrosis, but the theory will not explain why the dilatation is of the pelvic type. If there is inflammation present from the inception of the disease, I think one would expect the hydronephrosis to be of the renal type owing to thickening and fibrosis of the pelvic wall; in a typical case of the renal type of hydronephrosis due to a calculus, this is the probable and, I believe, the usually accepted reason why the pelvis does not dilate, for it is chronically inflamed and thickened around the stone; this is not only so when the stone is in the pelvis, but also when it has slipped further down the ureter (Fig. 9). To digress for a moment to the gall-bladder, a parallel may be drawn—in cases of obstruction to the common bile-duct where there is a diseased, that is a chronically inflamed gall-bladder, the latter does not dilate as it does when it is healthy, this condition, of course, being seen, for example, in cases of malignant obstruction to the comm duct. It seems more probable that the infla mation which is so often associated with hydr nephrosis is not primary and is not the cause the condition, but that it is the result of so stagnation of urine within the pelvis, and therefore, secondary to the hydronephrosis. As h already been mentioned, in some of these cases the pelvic type of hydronephrosis, the pelvi-urete junction is not obstructed, though in others there is narrowing, and sections at this point show signs chronic inflammation. Now if the hydronephrosis due to an achalasia, as I believe, when the infecti which is secondary to the stagnation of urine occu there will be an inflammatory thickening not only the renal pelvis but also of the adjacent portion the upper end of the ureter. As time goes on and t pelvis dilates it becomes so stretched that an app ciation of the inflammatory thickening is lost, wh the pelvi-ureteric junction still shows this thickeni and so to some extent narrowing, because it does n dilate owing to its want of muscular relaxation achalasia. Now is there any further explanati why the pelvis would dilate in cases of achalasi Can it be associated with some irregularity of nervo control ?

FIG. 9.



Renal type of hydronephros with calculus in ureter. Th renal pelvis is not dilated.

THE NEUROMUSCULAR MECHANISM.

The nerve-supply of the pelvis and ureter com from the renal plexus; the spermatic and hypogast plexuses also supply the ureter in its lower pa There seems no doubt that there is a parasympathet as well as a sympathetic nerve-supply; Kuntz from his extensive studies of the autonomic nervo system, says it is abundantly supplied by nerves bo of sympathetic and parasympathetic origin, but th rôle is little understood. From the action of vario drugs on the ureter, Macht[20] concludes that the is evidence of innervation by the true sympathet system and the parasympathetic system, and t response of the ureter to nicotine points to the presence of ganglion cells in its wall. Like other smooth muscle viscera, the ureter and pelvis possess the inherent capacity to undergo rhythmic contraction, but their activity is probably subject to regulating nervous impulses. The dynamic theory, as it has been called, attributes the cause of hydronephrosis to "primitive disorders of the pyelo-ureteral peristalsis." The experimental investigations of Blatt[21] appear to show that the peristalsis of the ureter, and of the pelvis, is regulated by the neuroganglionic motor centres placed within its wall; and that the lesion of these centres gives place to pyelo-ureteral dilatation by paralysis and muscular atony. Such a lesion would account for the dilatation affecting mainly the pelvis, and the calices only to a lesser degree. Can the condition be due to some lesion of the autonomic nervous system? Overaction of the sympathetic control of a muscular tube produces a relaxation of the tube with failure of relaxation of the sphincter below. Now if this condition were present it might well produce a hydronephrosis; there would be an obstruction at the functional sphincter of the pelvi-ureteric junction, and dilatation of the pelvis would take place more readily than of the kidney owing to the abnormality in its nervous control. Harris and Harris,[22] of Sydney, have performed renal sympathectomy in a number of cases, some of which showed dilatation of the renal pelvis. It is true that these cases mostly had pain, a thing which is so often absent in the early stages of hydronephrosis. These patients obtained relief from their symptoms.

Therefore, in an endeavour to suggest a cause for this condition of hydronephrosis, it seems to be necessary to attribute it to some disturbance of the neuromuscular mechanism, mainly because no other explanation appears to account either for the special dilatation of the pelvis or the presence of dilatation, in some cases, without mechanical obstruction. And it is believed that the various causes which have been or are put forward from time to time are secondary to the hydronephrosis and not the primary cause.

There is scarcely a disease in the whole of medicine the exact cause of which is known. In this respect, therefore, hydronephrosis falls into line with most other diseases. It seems probable, however, that in the case of hydronephrosis help is most likely to come from further investigations into the anatomy, physiology, and pathology of the neuromuscular mechanism of the renal pelvis and ureter.

THE TREATMENT OF RHEUMATOID ARTHRITIS WITH GOLD SALTS INJECTIONS.

By Jacques Forestier, M.D. Paris,
PHYSICIAN OF THE HOSPICE REINE-HORTENSE, AIX-LES-BAINS.

The treatment of rheumatoid arthritis is without doubt one of the most difficult problems in modern medicine, and in spite of the improvement in recent years the number of invalids due to this disease in most countries remains very high, and causes considerable expense to the States. The treatment of arthritis by physiotherapy undoubtedly remains one of the best methods, but the recent introduction of shock therapy has been an advance, and this has been followed by the extensive use of vaccines. The treatment is based on the fact that rheumatoid arthritis is in most cases due to an infective organism. Although some physicians differentiate between true rheumatoid arthritis—a disease affecting mostly women during the child-bearing period, and accompanied by intense vasomotor disturbances—and infective arthritis, occurring in old people causing little vasomotor disturbances, there does not seem to be any distinct difference between those forms.

Stock vaccines have been tried on a small scale in France, mostly streptococcal, but autogenous vaccines in England have not met with much enthusiasm. This treatment, which was once favourably accepted in England and the United States, seems to have led to disappointment. Most of these vaccines are collected from infective foci, which is not really a scientific method and does not produce the "pathogenic organisms" which cause the disease.

Recently treatment with chemical compounds has been tried: iodine intravenously; ammonium orthoxybenzoate in the United States, and iodalcoylates in France. This method gave some favourable results, but the need to repeat daily injections during months has robbed it of its practical value.

Chemotherapy has always appeared to me likely to be of great help in treating rheumatoid arthritis, since it is efficient in infective diseases, such as syphilis or tuberculosis. A certain amount of similarity between the latter disease and rheumatoid arthritis—i.e., impairment of the general condition, anæmia, leucocytosis, and temperature—led me to believe that some forms of treatment which had proved valuable for tuberculosis could help in the treatment of rheumatoid arthritis. This is why in 1928 I began to treat such patients with gold salts, the method introduced in treating pulmonary tuberculosis by Mollgaard in 1914. Only after I had commenced my work did I hear of the experiments of Feldt in Germany, who showed the curative action of injections with gold salts for experimental streptococcal infections in rabbits.

The gold compound which we have used is not the thiosulphate of sodium and gold used by Mollgaard and known in medicine under the name of sanocrysin, which can be used only intravenously. We have injected sodium aurothiopropanol sulfonate, which has been produced by A. Lumière, and is known under the name of allochrysine; its chemical formula is:

$$\begin{array}{ll} CH_2—SAu & CH_2—SH \\ CH—OH & CH—OH \\ CH_2—SO_3Na & CH_2—SO_3Na \end{array}$$

There is a direct connexion between the gold and the sulphur which does not exist in thiosulphate. Allochrysine is slightly toxic, the lethal dose being 10 cg. per kg. in the case of a guinea-pig.

The gold salts treatment has proved of great value in all forms of infective and rheumatoid arthritis. We have especially directed our attention to the severe forms of the disease when numerous joints were affected, very often symetrically. Out of 48 cases, the result of which we shall report, only 40 per cent. were cases of less than two years' duration, 30 per cent. were of two to five years' duration, and 30 per cent. were of over five years' duration. In the first class of cases, where the disease is still in its infancy, there are synovial changes only, while cartilages and bones are still unaffected. When therefore the progress of the arthritis is stopped, recovery is complete, while in the older cases, when changes in the cartilages, displacements, and subluxations have taken place, there always remains a certain amount of functional impairment, even when the disease has been arrested.

LABORATORY TESTS.

Clinically we have found a moderate increase of temperature in 35 out of 48 patients; in only 10 per cent. of them was it possible to detect a definite focus which could be regarded as the cause of the disease. We have done a considerable amount of bacteriological research in the natural cavities of our patients and have made blood cultures; no great results were observed in spite of the fact that we frequently found streptococci, mostly of the *viridans* type, in the cavities; blood cultures were constantly negative.

We have observed in most of our cases a moderate anæmia and a definite leucocytosis, sometimes more than 20,000 per c.mm., a finding which confirms the investigations of Kahlmeter in Sweden. (Table I.) But the most striking feature of the changes in the blood of our patients was that of the resorcin flocculation test of Vernes, and of the sedimentation rate of the red corpuscles.

TABLE I.—*Hæmatological Examination Before and After Treatment (18 Cases).*

		Red corpuscles in millions per c.mm.			Leucocytes in thousands per c.mm.		
Corpuscles.		*3 to 4*	*4 to 5*	Above 5	*5 to 10*	*10 to 15*	Above 15
Cases	Before	5	14	0	1	6	12
	After	4	15	0	6	11	2

The resorcin flocculation test, which in a normal subject is below 30 with the Vernes method, has been over 40 in 80 per cent. of our cases, and sometimes up to 80 and 120. The sedimentation rate of the red corpuscles tested with the Westergren method is in normal subjects 3 to 6 mm. in one hour; it shows normal figures in osteo-arthritis, neuritis, and fibrositis. In rheumatoid arthritis, during the progress of the disease, 20 per cent. of the patients show figures between 20 and 30 mm., 30 per cent. between 30 and 50, 26 per cent. between 50 and 80, 5 per cent. being above this figure, sometimes up to 120 mm. Only 16 per cent. are between 20 mm. and 10 mm., which is already abnormally high, the average figure being 42 mm.

These two tests, which are not specific and are generally positive in infectious diseases and in tuberculosis, are most useful, not only from the diagnostic point of view but from the point of view of prognosis, and we test the blood of our patients at regular intervals to follow the effects of the treatment.

Other tests on the blood of these patients are generally negative; there is a slight exception with the complement-fixation test for gonococcus, which we have performed in a certain number of cases and which may be slightly or strongly positive in about 10 per cent. of the cases, sometimes quite unexpectedly. Our experience in this respect is still too limited, and we cannot draw definite conclusions, as Léri has done lately, but as far as the Wassermann test and the other serological tests for syphilis are concerned, they have been constantly negative, and our personal experience has been confirmed by our findings at the Cochin Hospital in Paris with Coste and Lacapère.

Syphilis does not seem to have any importance in the ætiology of rheumatoid arthritis; it would be very desirable to make a serological test for tuberculosis, but unfortunately none of the available methods can be considered specific. The resorcin test has been proposed by Vernes for the diagnosis of tuberculosis. The increase in the sedimentation rate has been observed in the same disease, but no definite conclusion can be drawn from it. Notwithstanding this, we are convinced that tuberculosis has more influence on the onset of rheumatoid arthritis than syphilis.

The result of chemical researches on the blood has been equally negative: in 24 cases we have had the following results:—

Urea.—Minimum, 0·28; maximum, 0·54; average 0·4 per 1000 c.cm.

Uric acid.—Minimum, 0·032; maximum, 0 072; averag 0·043 per 1000 c.cm.

Cholesterin.—Minimum, 1·57; maximum, 2·40; averag 1·80 per 1000 c.cm.

These figures prove our statement that there i *no gross metabolic change.* In 15 cases where th basal metabolism was tested we did not find figure outside the normal limits.

METHOD OF TREATMENT.

Patients intended for treatment with gold salt after having undergone a careful clinical examinatio were submitted to the various tests which we hav described, and the best results seem to have followe when there was a slight increase in temperatur moderate leucocytosis, and an increased sedimentatio rate. Where some definite focal infection wa detected, it was attended to before starting th treatment with gold salts; teeth were extracte and infected nasal sinuses cleaned up; in tw instances tonsils were removed.

The injections of allochrysine were given intra muscularly, generally into the gluteal muscles, an did not cause any pain or local reaction. The firs series consists of three injections of 5 cg. at an interv of five days; if these injections do not cause an reaction, the series is continued by weekly injectio of 10 cg. up to a total of 1·50 g. or 2 g., dependin on the tolerance. Such a series lasts about thre months. No more than 2 g. are given, and the dail dose should not exceed 2 cg., to prevent any tox effect—for example, 5 cg. every fifth day would mea a daily dose of 1 cg.; 10 cg. every fifth day woul mean a daily dose of 2 cg. When this first series completed it is essential to give the patient a re from any injections for six or eight weeks; afte this period a second series similar to the first is give with the same rest interval at the end. When a result has been obtained it is essential to continue the treatment by subsequent series of 10 to 20 weekly injections of 10 or 5 cg. for a year or two.

The effect of the treatment is controlled by careful clinical examination and a study of the changes in the temperature curve, when there is a moderate temperature, but the best control is undoubtedly the blood examination. The decrease in the white blood corpuscles is a good prognostic sign, but even better is the decrease of the sedimentation rate of the blood corpuscles. This is the most reliable and sensitive test for the control of the treatment; whenever the sedimentation rate remains decidedly high, above 20 mm. for the first hour, it is certain that the progress of the disease has not stopped.

On the other hand, we consider that a patient affected with rheumatoid arthritis in whom the sedimentation rate has come back to normal figures (under 10 mm. during the first hour) may be considered cured if these normal figures have been constant for over a year after the completion of the treatment. We advise testing the sedimentation rate of the patients during the treatment at least once a month and, later on, once every second month.

STATISTICAL TABLES.

We have treated up to the present over 100 patients by this method, but we shall take into consideration only 48 cases which we have been able to observe and treat over a sufficient length of time. In such a chronic disease as rheumatoid arthritis, one cannot claim any success for a treatment unless two years have elapsed during which time results are thoroughly checked.

CLINICAL RESULTS.

The action of the gold salt treatment does not appear very quickly to clinical examination; at least two or three months elapse before definite changes in the condition of the patient are observed.

The effect on the general condition is generally very remarkable; a high percentage of our rheumatic patients were pale, with a sallow café au lait colour. After three months' treatment their colour became normal and they looked much stronger and less depressed.

The action on the joints is different in cases of short and long standing; in the first, when there was only a synovial swelling, this disappeared progressively in two or three months in favourable cases and the joints became completely normal again. In the older cases, where subluxations and stiffness accompanied chronic inflammation of the joints, the latter changes disappeared but the former were only slightly modified.

The main cause of invalidity among rheumatic patients is the pain on active and passive movements; this progressively diminished after one month or more, and from that time the movements of the different joints were greatly improved. Three patients who had been bedridden for four to six years were able to stand up and walk a few steps after the first series of treatment. By judging the amount of aspirin which patients take for their pains, so that they can go about their daily life, one can observe any improvement which takes place. In our experience two out of three of our patients who were taking six to eight tablets of grs. x every day could come down little by little to one or two tablets, and later on were able to discard them entirely. The body-weight showed in some cases an increase of a few pounds, but other patients lost a little weight when they were able to make a larger amount of physical exertion.

Like the treatment with mercury, bismuth, and arsenic, the gold salts also may cause reactions against which one should be on guard. Sometimes an increase of temperature and temporary rashes may occur; these appear in certain sensitive patients for no reason, and could be considered as anaphylactic phenomena; they did not prevent us from continuing the treatment.

Sometimes after six to eight injections toxic changes occurred. They consisted of two kinds: those on the mouth and those on the skin. We observed in 20 per cent. of cases a mild form of stomatitis with erosion of the lips and tongue, which was only severe in four cases. The skin reactions were mostly morbilliform rashes, and in five instances erythrodermia with subsequent desquamation. These various changes have been observed in 13 out of 26 cases, at the beginning of the experiment, when we were using daily doses which were three times or twice as large as that we have described. With our usual doses they occur very seldom (3 out of 22 cases), and they are of the very benign type provided one is careful. One should always ask the patient when an injection is to be made whether the preceding one has caused any irritation in the mouth or on the skin; if there is the least doubt about it, the next injection should not be given, and a sufficient length of time should elapse before the treatment is resumed. To prevent any affection of the mouth, the patients should clean their teeth with a tooth-paste containing arsenic.

EFFECTS OF THE GOLD TREATMENT.

The following results have been obtained after an experience of three years. Altogether they may be considered as very satisfactory considering the percentage of cases which have been not only greatly improved but almost clinically cured. Table II. sums up the results.

Very good results have been obtained in 17 cases; the patients were clinically free from symptoms, and every sign of progress of the disease disappeared in cases of short duration. In some cases we were so fortunate as to restore the use of the limbs, and the swelling of the joints disappeared, but as rheumatoid arthritis may persist for several years one does not feel justified in speaking of a cure.

TABLE II.—*Results of Gold Salts Treatment* (*48 Cases*).

Results.	Total dose.					Total.	Insufficient treatment.
	Below 1 g.	1 to 2	2 to 3	3 to 4	Above 4		
Negative ..	—	—	—	—	1	1	4
Moderate ..	3	4	1	—	2	10	—
Good ..	1	6	4	—	5	16	—
Very good.	2	4	3	4	4	17	—
Total cases	6	14	8	4	12	44	4

The very good cases and good cases number 33, or 70 per cent., and this percentage can be considered as a definite advance in the treatment of rheumatoid arthritis. The balance of our cases include ten partial results and five negative results. In three cases there was a temporary improvement followed by a relapse; of the disappointing results, most of the patients had not had sufficient treatment for one reason or another; in only one of them had the

There is a direct connexion between the gold and the sulphur which does not exist in thiosulphate. Allochrysine is slightly toxic, the lethal dose being 10 cg. per kg. in the case of a guinea-pig.

The gold salts treatment has proved of great value in all forms of infective and rheumatoid arthritis. We have especially directed our attention to the severe forms of the disease when numerous joints were affected, very often symetrically. Out of 48 cases, the result of which we shall report, only 40 per cent. were cases of less than two years' duration, 30 per cent. were of two to five years' duration, and 30 per cent. were of over five years' duration. In the first class of cases, where the disease is still in its infancy, there are synovial changes only, while cartilages and bones are still unaffected. When therefore the progress of the arthritis is stopped, recovery is complete, while in the older cases, when changes in the cartilages, displacements, and subluxations have taken place, there always remains a certain amount of functional impairment, even when the disease has been arrested.

LABORATORY TESTS.

Clinically we have found a moderate increase of temperature in 35 out of 48 patients; in only 10 per cent. of them was it possible to detect a definite focus which could be regarded as the cause of the disease. We have done a considerable amount of bacteriological research in the natural cavities of our patients and have made blood cultures; no great results were observed in spite of the fact that we frequently found streptococci, mostly of the *viridans* type, in the cavities; blood cultures were constantly negative.

We have observed in most of our cases a moderate anæmia and a definite leucocytosis, sometimes more than 20,000 per c.mm., a finding which confirms the investigations of Kahlmeter in Sweden. (Table I.) But the most striking feature of the changes in the blood of our patients was that of the resorcin flocculation test of Vernes, and of the sedimentation rate of the red corpuscles.

TABLE I.—*Hæmatological Examination Before and After Treatment (18 Cases).*

		Red corpuscles in millions per c.mm.			Leucocytes in thousands per c.mm.		
Corpuscles.		3 to 4	4 to 5	Above 5	5 to 10	10 to 15	Above 15
Cases	Before	5	14	0	1	6	12
	After	4	15	0	6	11	2

The resorcin flocculation test, which in a normal subject is below 30 with the Vernes method, has been over 40 in 80 per cent. of our cases, and sometimes up to 80 and 120. The sedimentation rate of the red corpuscles tested with the Westergren method is in normal subjects 3 to 6 mm. in one hour; it shows normal figures in osteo-arthritis, neuritis, and fibrositis. In rheumatoid arthritis, during the progress of the disease, 20 per cent. of the patients show figures between 20 and 30 mm., 30 per cent. between 30 and 50, 26 per cent. between 50 and 80, 5 per cent. being above this figure, sometimes up to 120 mm. Only 16 per cent. are between 20 mm. and 10 mm., which is already abnormally high, the average figure being 42 mm.

These two tests, which are not specific and are generally positive in infectious diseases and in tuberculosis, are most useful, not only from th diagnostic point of view but from the point of vie *of prognosis, and we test the blood* of our patien at regular intervals to follow the effects of th treatment.

Other tests on the blood of these patients a generally negative; there is a slight exception wi the complement-fixation test for gonococcus, whi we have performed in a certain number of cases a which may be slightly or strongly positive in abo 10 per cent. of the cases, sometimes quite une pectedly. Our experience in this respect is still t limited, and we cannot draw definite conclusions, Léri has done lately, but as far as the Wasserma test and the other serological tests for syphilis concerned, they have been constantly negati and our personal experience has been confirn by our findings at the Cochin Hospital in Paris w Coste and Lacapère.

Syphilis does *not seem to* have any importa in the ætiology of rheumatoid arthritis; it wo be very desirable to make a serological test tuberculosis, but unfortunately none of the availa methods can be considered specific. The reso test has been proposed by Vernes for the diagn of tuberculosis. The increase in the sedimentat rate has been observed in the same disease, but definite conclusion can be drawn from it. Notw standing this, we are convinced that tubercul has more influence on the onset of rheumat arthritis than syphilis.

The result of chemical researches on the blood been equally negative: in 24 cases we have had following results:—

Urea.—Minimum, 0·28; maximum, 0·54; average per 1000 c.cm.
Uric acid.—Minimum, 0·032; maximum, 0·072; av 0·043 per 1000 c.cm.
Cholesterin.—Minimum, 1·57; maximum, 2·40; ave 1·80 per 1000 c.cm.

These figures prove our statement that ther no gross metabolic change. In 15 cases where basal metabolism was tested we did not find fig outside the normal limits.

METHOD OF TREATMENT.

Patients intended for treatment with gold s after having undergone a careful clinical examina were submitted to the various tests which we described, and the best results seem to have foll when there was a slight increase in tempera moderate leucocytosis, and an increased sedimenta rate. Where some definite focal infection detected, it was attended to before starting treatment with gold salts; teeth were extra *and infected nasal sinuses cleaned up;* in instances tonsils were removed.

The injections of allochrysine were given i muscularly, generally into the gluteal muscles, did not cause any pain or local reaction. The series consists of three injections of 5 cg. at an int of five days; if these injections do not cause reaction, the series is continued by weekly injec of 10 cg. up to a total of 1·50 g. or 2 g., depen on the tolerance. *Such a series lasts about* t months. No more than 2 g. are given, and the dose should not exceed 2 cg., to prevent any t effect—for example, 5 cg. every fifth day would n a daily dose of 1 cg.; 10 cg. every fifth day w mean a daily dose of 2 cg. When this first seri completed it is essential to give the patient a from any injections for six or eight weeks; this period a second series similar to the first is gi with the same rest interval at the end. When a result has been obtained it is essential to continue the treatment by subsequent series of 10 to 20 weekly injections of 10 or 5 cg. for a year or two.

The effect of the treatment is controlled by careful clinical examination and a study of the changes in the temperature curve, when there is a moderate temperature, but the best control is undoubtedly the blood examination. The decrease in the white blood corpuscles is a good prognostic sign, but even better is the decrease of the sedimentation rate of the blood corpuscles. This is the most reliable and sensitive test for the control of the treatment; whenever the sedimentation rate remains decidedly high, above 20 mm. for the first hour, it is certain that the progress of the disease has not stopped.

On the other hand, we consider that a patient affected with rheumatoid arthritis in whom the sedimentation rate has come back to normal figures (under 10 mm. during the first hour) may be considered cured if these normal figures have been constant for over a year after the completion of the treatment. We advise testing the sedimentation rate of the patients during the treatment at least once a month and, later on, once every second month.

STATISTICAL TABLES.

We have treated up to the present over 100 patients by this method, but we shall take into consideration only 48 cases which we have been able to observe and treat over a sufficient length of time. In such a chronic disease as rheumatoid arthritis, one cannot claim any success for a treatment unless two years have elapsed during which time results are thoroughly checked.

CLINICAL RESULTS.

The action of the gold salt treatment does not appear very quickly to clinical examination; at least two or three months elapse before definite changes in the condition of the patient are observed.

The effect on the general condition is generally very remarkable; a high percentage of our rheumatic patients were pale, with a sallow café au lait colour. After three months' treatment their colour became normal and they looked much stronger and less depressed.

The action on the joints is different in cases of short and long standing; in the first, when there was only a synovial swelling, this disappeared progressively in two or three months in favourable cases and the joints became completely normal again. In the older cases, where subluxations and stiffness accompanied chronic inflammation of the joints, the latter changes disappeared but the former were only slightly modified.

The main cause of invalidity among rheumatic patients is the pain on active and passive movements; this progressively diminished after one month or more, and from that time the movements of the different joints were greatly improved. Three patients who had been bedridden for four to six years were able to stand up and walk a few steps after the first series of treatment. By judging the amount of aspirin which patients take for their pains, so that they can go about their daily life, one can observe any improvement which takes place. In our experience two out of three of our patients who were taking six to eight tablets of grs. x every day could come down little by little to one or two tablets, and later on were able to discard them entirely. The body-weight showed in some cases an increase of a few pounds, but other patients lost a little weight when they were able to make a larger amount of physical exertion.

Like the treatment with mercury, bismuth, and arsenic, the gold salts also may cause reactions against which one should be on guard. Sometimes an increase of temperature and temporary rashes may occur; these appear in certain sensitive patients for no reason, and could be considered as anaphylactic phenomena; they did not prevent us from continuing the treatment.

Sometimes after six to eight injections toxic changes occurred. They consisted of two kinds: those on the mouth and those on the skin. We observed in 20 per cent. of cases a mild form of stomatitis with erosion of the lips and tongue, which was only severe in four cases. The skin reactions were mostly morbilliform rashes, and in five instances erythrodermia with subsequent desquamation. These various changes have been observed in 13 out of 26 cases, at the beginning of the experiment, when we were using daily doses which were three times or twice as large as that we have described. With our usual doses they occur very seldom (3 out of 22 cases), and they are of the very benign type provided one is careful. One should always ask the patient when an injection is to be made whether the preceding one has caused any irritation in the mouth or on the skin; if there is the least doubt about it, the next injection should not be given, and a sufficient length of time should elapse before the treatment is resumed. To prevent any affection of the mouth, the patients should clean their teeth with a tooth-paste containing arsenic.

EFFECTS OF THE GOLD TREATMENT.

The following results have been obtained after an experience of three years. Altogether they may be considered as very satisfactory considering the percentage of cases which have been not only greatly improved but almost clinically cured. Table II. sums up the results.

Very good results have been obtained in 17 cases; the patients were clinically free from symptoms, and every sign of progress of the disease disappeared in cases of short duration. In some cases we were so fortunate as to restore the use of the limbs, and the swelling of the joints disappeared, but as rheumatoid arthritis may persist for several years one does not feel justified in speaking of a cure.

TABLE II.—*Results of Gold Salts Treatment* (48 *Cases*).

Results.	Total dose.					Total.	Insufficient treatment.
	Below 1 g.	1 to 2	2 to 3	3 to 4	Above 4		
Negative ..	—	—	—	—	1	1	4
Moderate ..	3	4	1	—	2	10	—
Good ..	1	6	4	—	5	16	—
Very good.	2	4	3	4	4	17	—
Total cases	6	14	8	4	12	44	4

The very good cases and good cases number 33, or 70 per cent., and this percentage can be considered as a definite advance in the treatment of rheumatoid arthritis. The balance of our cases include ten partial results and five negative results. In three cases there was a temporary improvement followed by a relapse; of the disappointing results, most of the patients had not had sufficient treatment for one reason or another; in only one of them had the treatment to be discontinued on account of an intolerance to the drug which had caused an increase of the joint symptoms and erythrodermia.

The patients who have been able to stand several series of treatments have got the best results, their total dose being 3, 4, or 5 g. of allochrysine; 9 out of 12 patients who received over 4 g. of gold salts have been considerably improved. Of the cases who received less than 1 g., 50 per cent. show poor results and 50 per cent. good results.

Judging the question from a clinical standpoint, we can state that after two series of 1·50 g. or 2 g. doses, it is useless to continue the treatment if the patient has not already obtained some definite improvement; when this improvement has been obtained, it is well worth while to continue the treatment, not only until the patient is free from symptoms, but for several months after the different biological tests, and especially the resorcin test and the sedimentation test, have come back to normal figures.

INDICATIONS AND CONTRA-INDICATIONS.

The treatment is justified in all cases of rheumatoid arthritis or infective peri-arthritis, as long as the disease is developing; its development is shown by clinical symptoms: pains, stiffness, swellings, disability, anæmia, and sometimes moderate increase of temperature, checked by blood examinations. Cases which respond best to the treatment are those accompanied by leucocytosis, high resorcin flocculation test, and accelerated sedimentation rate. Such cases of rheumatoid arthritis may be treated with great success in almost 70 per cent. of cases and with practically no danger, provided the liver and kidneys are in good condition and the blood pressure is not exceedingly high.

We have treated young patients and old patients. One patient over 70 responded favourably to small doses of 5 cg. per week; it is common to find that the development of arthritis in old people is not so severe as in middle-aged people.

Albuminuria.—Gold salts are contra-indicated in cases where tests show that the function of the kidney is greatly impaired.

Osteo-arthritis.—Whatever its localisation may be —hip, knee, or phalanges—osteo-arthritis is quite a different disease from rheumatoid arthritis, and where the blood is practically normal from the point of view of leucocytosis, the resorcin flocculation test and sedimentation rate, the gold treatment is not indicated. The same may be said of neuritis and fibrositis.

We do not consider that gold salts treatment should be given without the other treatments for arthritis, especially massage with active and passive movements; all kinds of physiotherapy prove of great value as an aid to the method. Hydrotherapeutic treatment—sulphur baths, douche-massage, mud baths—has been used by 60 per cent. of our patients, and has certainly helped to bring about a rapid improvement of the functions.

The method cannot be compared with shock therapy, as it does not cause any such reaction in most of the cases; it seems to be much nearer to the Metalsalt therapy which has been suggested by Walbum, of Copenhagen, from animal experiments.

In all the reported cases treatment has been given in the form of allochrysine injected intramuscularly; in a limited number of other cases which are not reported here, we have used thiosulphate of sodium and gold (sanocrysin, Crisalbine) injected intravenously; the results have been almost the same. We believe that the active element in those preparations is the metal gold, which is chemically combined with the sulphur, re-inforcing its action; those two chemical compounds of gold, sanocrysin and allochrysine, improve the action of the metal just as salvarsan improves the action of arsenic. Where colloidal gold has failed, allochrysine succeeds; it may be regarded as the best chemical for the treatment of rheumatoid arthritis.

THE DETECTION OF PRESYMPTOMATIC TUBERCULOSIS IN CHILDREN.

By Ernest Fletcher, M.B. Camb., M.R.C.P. Lond.,

ASSISTANT PHYSICIAN, QUEEN MARY'S HOSPITAL FOR THE EAST END; PHYSICIAN, CHILDREN'S CONSULTATION CENTRE, MARYLEBONE GENERAL DISPENSARY; MEDICAL REGISTRAR, ROYAL HOSPITAL FOR DISEASES OF THE CHEST.

The trend of modern work in tuberculosis lies largely in the direction of early diagnosis. Ideally, the infection must be detected before symptoms appear, for treatment at this stage holds out great hope of complete cure. In the case of children, radiology and the tuberculin test are the two most important means of securing early recognition.

In 1930 Kerley[1] read a paper to the British Institute of Radiology, in which he described the radiological appearances. His work, however, was done among patients of the Royal Chest Hospital, so that he was necessarily dealing with people who were ill and knew they were ill. *It is not among these that we must look primarily for the presymptomatic stages of tuberculosis.*

In order to investigate normal children, I selected 50 cases from the children's consultation centre at the St. Marylebone General Dispensary, who, although they had in times past attended th dispensary for various ailments, were at the time o their examination, so far as they or their parent knew, healthy. In order to obviate, as far as possible the objection that this is not a series of health children, Table I. shows the ailments for which thes children originally attended the dispensary. A glanc at Table I. suggests that there can be few childre who have not, at some time, attended a doctor or a hospital for ailments of this type.

TABLE I.

Ailments.	Children.	Ailments.	Children.
Cough	9	For examination ..	6
Nasal catarrh ..	4	Under weight ..	6
Tonsillitis	6	"Nerves"	2
Headaches	2	Glands in neck ..	1
Wax in ears ..	1	Enuresis	1
Scoliosis	1	Erratic behaviour ..	3
Diarrhœa and vomiting	1	Strabismus	1
Fractured humerus ..	1		
Poor appetite ..	*5*		*50*

In no case had the *original examination* revealed any sign of organic disease. These children were chosen because they were the first 50 children on the follow-up list who had not attended the Dispensary recently; they all came from London boroughs.

EXAMINATION ROUTINE.

The same routine was followed in each case. A thorough clinical examination was made, and any statements as to the child's health by the parent were duly recorded. The child was then sent for radiological examination. If either of these examinations showed anything abnormal, a tuberculin test was done.

Perhaps a note of explanation is needed here. The tuberculin test is usually considered the method of choice when sorting out children for these investigations. In most cases the test is done, the children are divided into two classes, reactors and non-reactors, and the investigation proceeds from this point. In other cases the test is done to pick out the non-reactors, and they are taken as showing signs or appearances which may be considered normal. Most authors follow this sequence on account of the expense involved in radiological examination of large numbers of children. It is somewhat difficult to determine the percentage of children who, reacting to tuberculin, also show radiological evidence of tuberculosis, as compared with those who, being non-reactors, still show radiographic evidence of the disease. But in view of findings[2, 3] at the Henry Phipps Institute in Philadelphia it seemed to me better to take X ray evidence as the starting point. In cases where there was any suspicion of non-tuberculous infection of the lung, a lipiodol injection was made.

For the purposes of this paper, those children who were found on clinical examination to have signs of bronchial catarrh, but whose radiological examination and tuberculin test were negative, have been classed as normals. Films were taken of each case. Where the term "fibrosis of the lungs" is used in this paper, non-tuberculous fibrosis is meant.

The *tuberculin test* was made intradermally by the method of Mantoux.[4] Pirquet's method has been repeatedly shown to give a smaller percentage of reactors. 0·1 c.cm. of 1 in 10,000 O.T. was injected intradermally; if no reaction followed, 0·1 c.cm. of 1 in 1000 was injected; if this again was negative, 0·1 c.cm. of 1 in 100 was injected, which is equivalent to 1 mg. A reaction which included a ring of erythema 10 mm. wide, with some œdema and raising of the skin, was classed as + ; if the ring was as large as 15 mm. it was classed as ++. No other type of reaction was found in the series. In practice no child actually reacted to the third dose who had not reacted to one of the first two.

Tubercle bacilli.—In no case were tubercle bacilli found in the sputum.

Ages.—The average age of the children of the series was 7·3 years. All except four were between the ages of 5 and 12.

RESULTS.

The results of the examination were as follows :—

Normals	37	(74 %)
Tuberculosis of childhood	4	(8 %)
Apical infections	—	—
Fibrosis of the lungs	5	(10 %)
Enlarged mediastinal glands	4	(8 %)
	50	(100 %)

That is to say, that out of 50 cases examined, 13 had demonstrable lesions of the lung, of which 8 were tuberculous and 5 were non-tuberculous.

Clinical examination.—The number of cases showing physical signs was 13. Of these, 9 showed scattered râles brought out on coughing only; 1 showed diminished air-entry to the right upper and middle lobes, and is classed as tuberculous; 3 showed impaired percussion note at one base with post-tussive crepitations, and are classed as fibrosis of the lungs.

The *tuberculin test* was done in 20 cases; of these 12 were positive and 8 were negative. Of the positives 7 were + and 5 were ++.

Of the 7 who were + : 1 was a case of fibrosis of the lungs (5); 2 were cases of tuberculosis of childhood (22, 37); 2 were cases of enlarged tracheo-bronchial glands (23, 27); and 2 were normals, one of whom had enlarged cervical glands (25, 12).

Of the 5 who were ++ : 1 was a case of tuberculosis of childhood; and 4 were apparently normals.

Of the 8 who were negative : 1 was a case of tuberculosis of childhood; 1 was a case of non-tuberculous fibrosis; 1 showed enlarged mediastinal glands; and 5 were normals.

The incidence of exanthemata and other diseases was as follows :—

	Measles.	Whooping-cough.	Lung infections.	Other diseases.
Normal group ..	81 %	62 %	44 %	10 %
Abnormal group	83 %	66 %	50 %	6 %

Table II. shows details of the cases classed as tuberculosis of childhood, enlarged glands, and non-tuberculous fibrosis.

Contacts.—Only one case (No. 5) gave a history of contact with open tuberculosis, and this proved to be a case of non-tuberculous fibrosis. The tuberculin reaction was +. Two cases gave a family history of tuberculosis. One proved to be a non-tuberculous fibrosis, and the other was a case of tuberculosis of childhood. One author states that 91 per cent. of cases showing latent tuberculous lesions had no history of contact.

Underweight.—The question of the relationship of underweight to tuberculous infection in children is not settled. The balance of evidence is that there is no connexion between the two. Barnard, Amberson, and Loew[5] say that in their series of children the smallest number of reactors to tuberculosis was in those children who were underweight. No definite connexion was found in the present series between underweight and latent tuberculosis, or enlarged mediastinal glands.

Percentage of lesions found.—In the present small series 16 per cent. of the cases showed either latent lesions or enlarged mediastinal glands. It must be borne in mind that the cases were selected for further examination by X rays, and not by the tuberculin test.

CLINICAL EXAMINATION.

Attempts have been made to discover signs or symptoms which may accompany a change of reaction to tuberculin. The signs described as pathognomonic of enlarged tracheo-bronchial glands are indefinite, and although one has repeatedly tried to make the diagnosis before the X ray picture was taken, the number of correct diagnoses is small. It proved possible to diagnose only one out of four cases of latent tuberculosis by clinical examination alone, and three out of five cases of fibrosis of the lungs. In the four cases of enlarged mediastinal glands there appeared to be no physical signs.

The results of the intracutaneous tests have been given. It will be seen that three out of four cases of latent lesions gave a positive test to 0·1 mg. Out of four cases of enlarged tracheo-bronchial glands, two gave a positive reaction and two gave a negative reaction to 1·0 mg. of O.T. Some authors advise the standardisation of tuberculin. The tuberculin used in this series was supplied by Burroughs and Wellcome, and is stated to be standardised by guinea-pig injection. Out of seven cases, all of them finally regarded as being almost certainly potentially or actually tuberculous, three, or 42 per cent., gave a negative reaction to a large dose of O.T. The test was not done in one case of enlarged glands.

TABLE II.

Case	Age and sex.	Family history.	Clinical examination.	Tuberculin test.	Result.	Remarks.
Cases of Tuberculosis of Childhood.						
3	3, F	Good.	Rhonchi both bases.	+ +	Resolution.	—

RADIOGRAPHY.

Cases of tuberculosis of childhood.—Out of the four cases described, two are of a similar nature (Nos. 8 and 37). In both cases serial films are shown, demonstrating the complete clearing of the lesion (Figs. 1 and 2). In Case 8 the lesion involves the base of the upper lobe of the left lung. The appearance is that of consolidation.

A first picture was taken on Nov. 10th, 1930, and ten days later a second picture (Fig. 1A) showed that the consolidation had increased in size very considerably; the shadow at the hilar end was much denser and extended right out to the radiological periphery of the lung, the direction being upwards and outwards, cutting the axillary border at the third rib. The child was put to bed, for it is uncertain whether consolidations of this type are going to retrogress. In one month the lesion had begun to clear. In an antero-posterior view it appeared to be stationary both at the hilar and peripheral ends, and to clear in the centre, the lower edge being still uniform. A picture one month later shows the consolidation cleared, except at the hilar end, and four weeks later the appearances are normal (Fig. 1B).

It seems that the consolidation was only just commencing when the child was first seen, for the second picture showed a spread. If this was so, the whole process of infection and resolution took place in slightly over three months.

The second case of the same type (No. 37) showed the consolidation in the right lung.

The first picture (Fig. 2A) shows the lesion involving the lung right out to the periphery; the second picture (Fig. 2B), three weeks later, shows almost complete retrogression. It seemed that the middle lobe was involved as well in this case, and the original picture appear indicate some involvement of the diaphragmatic ple The whole lesion completely resolved, and a lipiodol injec made five months later shows no involvement of the bro There was stated to be some loss of weight in this c but it is difficult to be sure on this point.

These two cases are similar in almost every resp except that one child was 12 years old and the ot was 5. The sudden onset without symptoms, the of clearing, and the uniform consolidation suggestive of a similar mechanism.

The third case (No. 22) is of a different orde

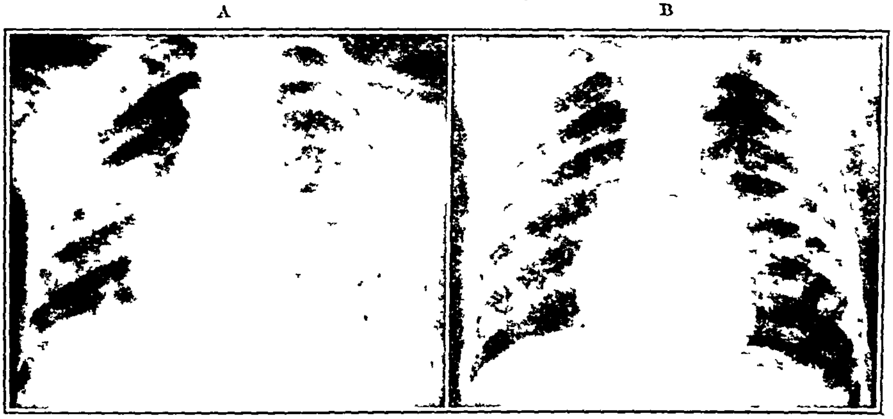
The child was a girl, aged 12, of delicate appeara The tuberculin reaction was +, and she had a fa history of pleurisy on the father's side, without any ac open tuberculosis. She said "she was always tired," had no actual symptoms apart from this. The radiolog appearances consisted of an area of soft infiltration u the second rib on the right side, only a few millimetre diameter, with involvement of the tracheo-bronchial gla Further, there was definite thickening of the interlo pleura. Five months later, the peripheral lesion completely cleared, and the interlobar pleura had resu its normal appearance. There was at this time radiological evidence of enlarged glands.

This child had occasionally been brought up by mother at irregular intervals, so that we had some rec of her weight over a period of time. There was no cha in the weight curve; it shows a perfectly steady rise all time.

The last case (No. 3) was a girl, aged 3, wit good family history. Her mother said she always had a cough, so that she took no notice of t t did not appear to be any worse than usual at the resent time.

The tuberculin reaction was ++. This child howed a wedge-shaped consolidation in the right ung, of uneven density, with mottled spots most oticeable at the level f the fourth rib in ront; spots of infiltration were present in the periphery of the lung at the same level. She has, I believe, gradually recovered, but I have no plate showing the appearances after resolution. There was no evidence of enlarged glands.

FIG. 2 (Case 37).

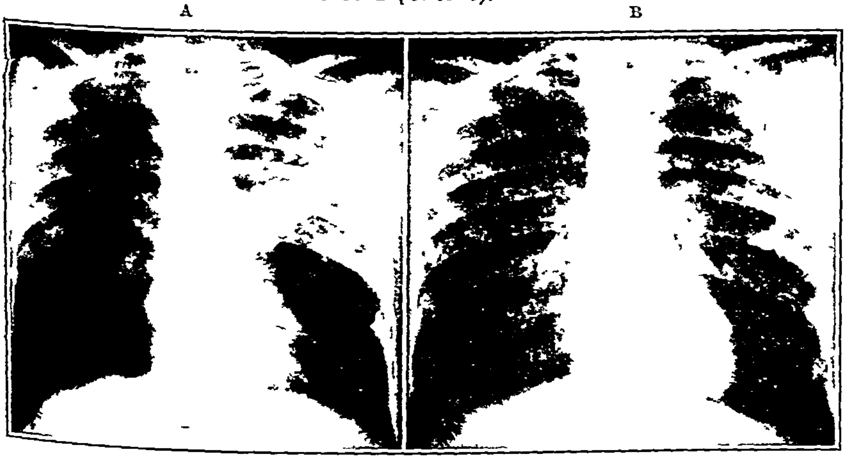


A, Large consolidation involving two and possibly three lobes of the right lung. Note tenting of the diaphragm. B, Five months later. The lesion has completely resolved

Cases of enlarged glands.—Of these, two (Nos. 23 and 27) are probably bilateral, and the other two are right-sided. Apart from the radiogram there was nothing to distinguish these cases. The two bilateral cases complained of being nervy or tired occasionally, and one child was very pale. The red cell count, however, was 5,000,000, and there was a relative lymphocytosis. The sedimentation curve was within normal limits.

Cases of fibrosis.—It is somewhat surprising to find so many early cases of fibrosis. Inasmuch as these are generally considered to be the result of past inflammations, I append a note of the number of attacks—pyrexial in nature and pulmonary in localisation—from which these children have suffered, as compared with the remainder of the series.

FIG. 1 (Case 8).



A, Large consolidation running upwards and outwards in the base of the left upper lobe. The consolidation is uniform, and reaches the radiological periphery of the lung. B, The condition three months later, showing the lesion completely cleared.

	No of attacks per child.
Fibrosis of the lungs	Average 3·0
Remainder	„ 1·8

These children have had slightly more than one attack over their share. This figure includes measles and whooping-cough.

CONCLUSIONS AND SUMMARY.

1. A survey has been made of 50 children, mostly of school age, who, although they have been patients at the Marylebone Dispensary, were at the time they were sent for considered healthy by their parents. Amongst the 50 have been found 4 cases of "latent tuberculosis" (tuberculosis of childhood), 4 of enlarged glands of the tracheo-bronchial group, and 5 of non-tuberculous fibrosis, making a total of 13 cases in all.

2. The tuberculin test gave the following results: of 4 cases of tuberculosis of childhood 1 was ++, 2 were +, and 1 was negative; of 4 cases of enlarged glands, 2 were +, 1 was negative, and 1 was not done. It is concluded, so far as it can be from such a small number, that the tuberculin test is no guide in a sufficiently important group of cases. As no case of tuberculosis of childhood developed, so far as is known, from contact with an open case of tuberculosis, it seems that there is still a large amount of accidental tuberculosis abroad—what the French call "tuberculose de la rue." In an American series,[5] 91 per cent. of children with radiological lesions had no history of exposure.

3. The probable period of development and resolution in favourable cases of "latent" tuberculosis in children is about three months.

4. The shape and extent of the lesion, by radiography, is apparently no guide to its severity, nor any indication of its prognosis.

5. Clinical examination and the tuberculin test are not altogether reliable guides to the presence of "latent" tuberculosis in children.

CHANGES IN THE LIVER OF MICE
FOLLOWING THE INGESTION OF HYDROCARBON OILS.

BY J. M. TWORT, B.SC. LOND.,
ZOOLOGIST TO THE MANCHESTER COMMITTEE ON CANCER:
AND
C. C. TWORT, M.D. ABERD.,
PATHOLOGIST TO THE COMMITTEE.

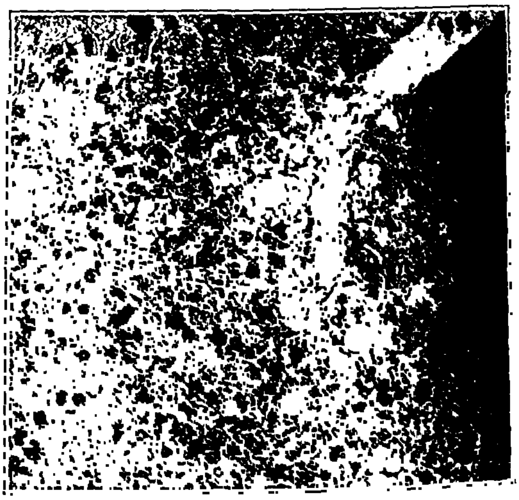
IN making an analysis of the results of many thousand post-mortem examinations of mice subjected to skin applications of various carcinogenic and non-carcinogenic agents we have been struck by certain microscopical changes which may at times be met with in the liver. We have, of course, encountered a great variety of diseases in the different organs of our animals, but the particular condition it is proposed to discuss is interesting in that it seems to be associated especially, although not solely, with mineral oil applications. The condition, hereafter called condition *x*, is depicted in the two accompanying microphotographs, which show the main features of the infiltrative process (Figs. 1 and 2).

The earliest indication seen microscopically that condition *x* may supervene is a periportal infiltration of small round cells with which may be intermixed a few polynuclears. Such an infiltration is very common in mice, and alone is of little significance for it precedes many other pathological changes in this animal. But we have noted that it seems to be always present to a greater or lesser degree in livers showing condition *x*. Later there appear, scattered throughout the organ as isolated members or in small groups, cells giving a definite but not intense bichromate reaction. They are easily distinguished from the round cells with which they may be intimately mixed. These cells vary in size, but are usually rather large, moderately well defined, with a reticular cytoplasm containing a central or eccentrically placed smallish, round or irregularly shaped nucleus staining densely with hæmatoxylin. They thus have the appearance of endothelial cells, and some of them are very similar to the characteristic cells found in xanthomas. In point of fact, however, we are at the present juncture not prepared to say anything definite as to their origin, except that they are seemingly not a product of the parenchyma cells but would appear to rise either from the capillary endothelium or from connective tissue; probably the former. The large cells increase in number, presumably in situ, forming conspicuous masses, but never large enough to be visible to the naked eye. Subsequently disintegration supervenes, this being first indicated by a foamy appearance of the cytoplasm, and later vacuolisation. Ultimately the cell is completely replaced by what is presumably a fat globule with the resulting microscopical picture of a type of fatty infiltration. There is unquestionably a certain amount of fat in the cell residue, but whether of saponifiable or hydrocarbon nature we cannot yet say. Investigations in this direction so far carried out do not exclude the possibility of hydrocarbon oils being associated with the animal fat which is present.

ORIGIN OF THE CONDITION.

Our attention was first drawn to this question on examining the livers of a batch of animals painted for a considerable period with a sulphur-treated shale oil, almost all of which showed condition *x* of the liver. We had previously met with the condition in many isolated specimens from animals treated with all sorts of agents, but although noted it was then looked upon as a chance fatty infiltration o little significance. As a result of our findings in th shale oil treated animals, we proceeded to examin the livers of animals treated for a similar perio of time with other agents, to try to find out whethe condition *x* was peculiar to shale oil treated animals The Table shows our findings in a few selected experiments, which will serve as examples of the kind o results to be expected.

FIG. 1.



Liver of mouse treated with Pennsylvanian spindle *oil*, showin typical infiltrative changes. (× 82.)

Substance applied.	Duration of exp. in weeks.	No. of animals.	Condition *x*.	Per cent
Diluted and acid treated shale oils	60	54	49	91
Refined shale oils	50	13	13	100
" " "	25	22	2	9
" " "	20	22	2	9
Shale oil residuum ..	50	16	1	6
Petroleum oil	60	49	38	77
" "	45	23	9	39
" "	40	125	40	32
Cotton-seed oil	50–90	25	0	0
Rape seed oil	50–70	7	0	0
Gas tar and synthetic tar..	40	30	0	0
[illegible]	25	68	0	0
[illegible]	45–60	321	154	48
[illegible]	40–80	130	0	0

The Table is almost self-explanatory. From ou preliminary observations it appears that gas tars synthetic tars, and saponifiable oils do not excit condition *x* of the liver. On the other hand an mineral *oil*, *disregarding* the degree of unsaturation seems capable of giving rise to the condition, provide

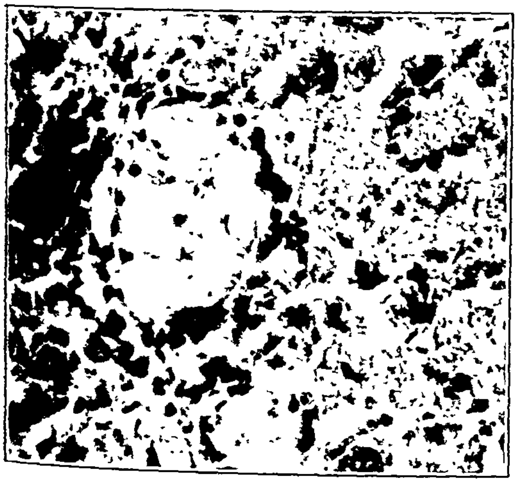
survival is sufficiently long to give the oil a chance of acting. However, it is not improbable that the extent of the disease may bear some relation to the degree of unsaturation of the hydrocarbons responsible, shale oils being very active in this respect. If medicinal liquid paraffin is considered to be completely saturated, then unsaturation does not seem to be the essential cause at work, for condition *x* of the liver apparently results from contact of animals with white mineral oils. Synthetic tars diluted with liquid paraffin twice induced condition *x*, as did very frequently spindle oils of mineral origin rendered non-carcinogenic by treatment with large amounts of sulphuric acid, and from which almost all the unsaturated compounds were consequently destroyed or rendered saturated. Needless to say, further experiments with medicinal liquid paraffin are now being undertaken to investigate more thoroughly the effect of such oil on the liver. It will be noted that only one out of the sixteen animals examined which were painted with the residuum of shale oil showed the condition, and consequently it appears that the toxic substances concerned may be mostly confined to the lighter boiling fractions of the oils we utilised. Also we are inclined to believe that the crude oils and oil extracts are less likely to lead to condition *x* of the liver than the refined oils; and in view of the inactivity of tars the possibility of inhibitory substances has to be considered. We are not at all certain that oils from all fields are similarly active. These questions will need further investigation, especially in relation to other pathological conditions which may mask or otherwise interfere with the infiltrative process with which we are concerned.

FIG. 2.



Liver of mouse treated with medicinal liquid paraffin and 25 per cent. shale oil, showing earlier stage than Fig. 1, with degenerating foamy xanthoma cells. (× 500.)

The duration of time of exposure and the amount of oil which finds its way into the organism are bound to be important factors, but as will be seen from the Table we have found that, at least with shale oil, it does not require many weeks to elapse before evidence of condition *x* is forthcoming.

Our examinations thus provided ample evidence that some of the hydrocarbons constituting the mineral oils utilised by us, or that some specific constituents, were capable of inducing condition *x* in the liver of our animals, while the specific constituents did not appear to be present in gas tars, synthetic tars or saponifiable oils.

A few quite recently examined livers have, however, rather complicated matters, although at the same time they have served to throw some light on the probable nature of the chemical substances responsible. Thus the livers of 5 out of 15 animals painted with oleic acid heated at 330° C. for 72 hours showed condition *x*. We attributed this result to the synthesis of hydrocarbons on heating the acid, but subsequently the condition was found in two animals painted with untreated oleic acid. Furthermore, we have twice encountered condition *x* of the liver among 23 specimens from animals painted with a fraction of our synthetic tar obtained by treatment with ethyl oxalate, resulting in the extraction of compounds with a reactive methylene group. The results with oleic acid fit in quite well with those given by mineral oils in view of this acid's chemical relation to the olefines, but that the particular aromatic compounds in the tar should induce condition *x* puts an altogether different aspect on the subject. It must be understood that although we have in no instance encountered condition *x* of the liver in unpainted animals, it is not to be assumed that a similar finding will not be met with among such animals. It must also be emphasised that our tar experiments are relatively of short duration, and it is very probable that animals painted over a longer period of time would provide specimens of condition *x* of the liver.

OTHER ORGANS AFFECTED.

We have mentioned the liver as if it were the sole organ affected, but we have occasionally seen in the spleen, suprarenal glands and ovary a condition which bears a good deal of resemblance to condition *x* of the liver. It is probable that the chemical substance responsible for this particular pathological change gains access to the internal organs by way of the alimentary tract and not by direct absorption by the skin. We have no very exact experimental data to bring forward in support of this assertion, but that the animals ingest much of the material painted on the skin is beyond dispute.

In connexion with these observations on the mouse, there are two papers which must be referred to. One is by C. J. Polson[1] on experimental liver necrosis induced by shale oil, and the second by H. J. Channon and G. A. Collinson[2] on the increase of non-saponifiable fats in the liver of rats and pigs fed on a synthetic diet containing medicinal liquid paraffin.

TRAINING OF SOCIAL WORKERS IN MENTAL HEALTH. A course in mental health is being arranged at the London School of Economics and Political Science to meet the needs of social workers whose services demand a more specialised knowledge of the causes and treatment of psychological difficulties than has hitherto been available in the general training in social science. The course lasts one year and includes both theoretical and practical training. Suitable candidates are admitted by a selection committee, preference being given to men and women who are over the age of 23, who hold a University certificate in social science, and have been engaged in social work. Consideration will be given to others with experience of responsible social work who, while they hold no University qualification, have reached a high standard of general education. With the help of the Commonwealth Fund of America the school is offering six scholarships to meet the expenses of students during training.

CLINICAL AND LABORATORY NOTES

ARTIFICIAL PNEUMOTHORAX.

TWO HUNDRED CASES.

BY JAMES D. MACFIE, M.B., CH.B. GLASG.,
SENIOR RESIDENT MEDICAL OFFICER, WINSLEY SANATORIUM;
AND
ARTHUR J. P. ALEXANDER, M.D.BELF., M.R.C.P.IREL.,
ASSISTANT RESIDENT MEDICAL OFFICER, WINSLEY SANATORIUM.

THE following figures summarise the results of cases of pulmonary tuberculosis treated by artificial pneumothorax at Winsley Sanatorium during the past seven years. These results are from selected cases where an artificial pneumothorax was employed after failure of routine sanatorium treatment to effect improvement, and deal mainly with cases of moderately advanced disease. They will not, therefore, be entirely comparable with American and Continental figures, for in Canada, America, and on the Continent many more early cases are subject to collapse therapy.

Artificial Pneumothorax Attempted in 200 Cases.

	Successful induction.	Failed to induce.	Total.
Alive	94 (57 %)	12 (38 %)	106 (53 %)
Dead	72 (43 %)	22 (62 %)	94 (47 %)
	166 (83 %)	34 (17 %)	

Class.	Gain or loss in weight.*	Alive.
Of 200 cases in which A.P. was induced—		
7 were in Class 1	Gained weight 47 % ; of these	77 %
53 ,, ,, 2	Lost weight 50 % ; of these	21 %
40 ,, ,, 3	Remained stationary 3 %	

* These figures are based on admission and discharge figures, the average duration of residence in hospital being 6¼ months.

Sputum. Before induction—
87 % of the patients were T.B. +
13 % ,, ,, ,, T.B. – or had no sputum.
On discharge—
54 % were T.B. + ; of whom 33 % are alive.
46 % ,, T.B. – or had no sputum ; of whom 65 % are alive.

Period since induction.	Nos. attempted, S = Successful; F = Failed.		Number. alive.	Per cent. alive.	Number dead.	Per cent. dead.
Under 6 mths. ..	22	S 17	15 + 1*	94	1*	6
		F 5	5	100	—	—

		F 5	—	—	5	100
4 to 6 yrs...	24	S 23	7	30	10* + 6	70
		F 1	—	—	1	100
6 to 7 yrs...	6	S 5	1	20	3* + 1	83
		F 1	—	—	1	100
Total ..	200					

* In cases so marked the treatment by refills had to be discontinued. (*a*) In those alive, because of adhesions causing failure to produce satisfactory collapse. (*b*) In those who died, owing to deterioration of condition.

A certain section of the profession is still sceptical about the value of the treatment, but even if in some cases the results are not permanent yet, to use the words of the late Dr. Clive Riviere, the prolongation of life, increased comfort and wellbeing, and return of power to work—and this for the most part among cases of advanced disease—entitle the operation of pneumothorax to a very high place among successful therapeutic measures.

RAPIDLY ADVANCING TETANUS SUCCESSFULLY TREATED WITH SERUM.

BY DAVID NABARRO, M.D., F.R.C.P.LOND.,
DIRECTOR OF THE PATHOLOGICAL DEPARTMENT, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON.

AUTHORITIES are by no means unanimous as to the
value of anti-tetanus serum in the treatment o
tetanus after the disease has clearly declared itsel
whereas the experience gained during the Great Wa
showed conclusively that as a prophylactic agains
tetanus the injection of antitetanic serum was ofte
of considerable value. Sir David Bruce[1] in a
analysis of 1000 cases of tetanus concluded tha
prophylactic inoculation of potential cases certainl
reduced the number of cases in which actual sympto
developed, prolonged the incubation period, an
diminished the rate of mortality in those in who
symptoms did develop. It has long been recognise
that the shorter the incubation period the high
is the mortality-rate, and in the cases analysed
Bruce the mortality-rate was 63·4 per cent. in cas
in which the incubation period was seven days
less, and 54 per cent. in which the incubation peri
was eight to fourteen days. Golla, criticising the
results, expressed the opinion that Bruce's figu
showed that the question of dosage did not h
at all in determining if serum had any therapeu
effect, while C. H. Browning said that Bruce's a
Golla's figures would seem to show the almost ut
uselessness of anti-tetanus serum as a therapeu
agent. This gloomy view was not supported, howe
by Sherrington's[2] observations of experimen
tetanus in monkeys, in which the best results w
obtained by introducing the serum subdur
by the lumbar or bulbar intrathecal routes.

CASE RECORD.

The following case presents several features
interest.

The patient, a boy aged 10 years, fell on a gravel
on June 9th, 1931, and injured his knee. Dr. A. E. Camp
of Guildford, attended to the injury, and at once cle
up the wound with iodine, and inserted one suture.
however, was removed next day because the wound
then suppurating. Dr. Campbell and his partner,
Arthur Mitchell, discussed the question of giving
tetanus serum and decided against it because the boy
fallen on a gravel path, which was unlikely to be inf
with tetanus. A few days later Mr. E. W. Sheaf, of Guild
saw the patient with Dr. Mitchell and discussed the ad
bility of opening up the wound, the question of anti-tet
serum being again discussed and the measure de
against. The temperature, which had never been hi
than 101° F., settled down, but began to rise agai
June 24th, when stiffness of the jaw was first not
Within an hour an injection of 13,000 units of anti-tet
serum was given intramuscularly. The wound was
examined on the 24th and a small sinus which cont
pus was laid open. Dr. R. C. Matson, pathologist t
Royal Surrey County Hospital, examined the disc
from the wound, but failed to find any evidence of te
in smears or by culture. At 10 A.M. on June 25th a se
dose of serum (20,000 units) was given intramuscu
and the boy appeared well, except that he took long
his breakfast owing to the stiffness of the jaws.

Dr. Eric Pritchard and I saw the boy shortly b
4 P.M. on that day, when trismus, opisthotonos,
risus sardonicus were well marked, while painful sp
of the abdominal muscles recurred at frequent short inter
These alarming symptoms had all come on rapidly
2 P.M. on that afternoon, possibly as the result of op
up the wound—which in the circumstances may
seemed desirable—and thereby liberating toxins into
system while there was little antitoxin present to neut

these. We decided not to examine him any further but to initiate serum treatment forthwith.

Under a general anæsthetic 20 c.cm. of perfectly clear cerebro-spinal fluid was withdrawn and 40.000 units of antitoxin in 13 c.cm. serum (B. W. & Co.) injected intrathecally. At the same time 40,000 units were injected intravenously and 40,000 units intramuscularly. Owing to the rapidity with which the symptoms had advanced that day, a very grave prognosis was given by Dr. Pritchard and the other medical men in attendance. At 5.30 P.M. chloretone, grs. 15, was given by rectum and at 7.45 P.M., as the opisthotonos and abdominal rigidity recurred, a further grs. 10 were given again by rectum. At 8.20 P.M. the patient was very collapsed and 0·2 g. of camphor in olive oil was injected subcutaneously. The wound was syringed hourly with eusol. The temperature rose to 102° F. at 10 P.M. but the patient passed a fair night. At 12.30 A.M., as the muscular spasms were frequent and severe, Dr. Mitchell and his partner, Dr. H. Bell, decided to give a subcutaneous injection of 20 c.cm. of a 25 per cent. solution of magnesium sulphate, and Dr. Bell, who remained with the patient for some hours to watch the effect, states that the spasms and muscular rigidity were definitely relieved by the injection.

On the morning of June 26th the boy complained of pain at the back of his neck, and in the eyes and abdomen, but the spasms were at longer intervals than on the previous day. At 12.30 P.M., under a general anæsthetic, lumbar puncture was again performed, the fluid spurting out under considerable pressure; about 30 c.cm. of turbid fluid was removed for subsequent examination, and 40.000 units of anti-tetanus serum in 13 c.cm. were given intrathecally and 60,000 units intramuscularly. Four rectal injections, each of chloretone grs. 10, were given during the ensuing 24 hours on account of restlessness or abdominal rigidity.

On June 27th I was unable to visit the patient and my colleague, Dr. A. Gordon Signy, kindly deputised for me. He reported that the rigidity had greatly diminished and there was no spasm of the jaw, but the abdomen was still boat-shaped. About 30 c.cm. of turbid cerebro-spinal fluid was again drawn off under pressure and 40,000 units of antitoxin in 13 c.cm. of serum diluted with 10 c.cm. of saline were injected intrathecally: at the same time 60.000 units were given intramuscularly. The patient was now obviously responding to the treatment, and on June 28th he was given 60,000 units intramuscularly by Dr. Mitchell; irritability and restlessness were treated with chloretone, grs. 5, when required.

On June 29th he was still rather irritable and complained of headache, so lumbar puncture was again performed. This time the fluid was not under pressure and was clearer than it had been; 25 c.cm. were removed and 20,000 units in 6·5 c.cm. +10 c.cm. of saline were injected intrathecally, and 60,000 units intramuscularly. The patient was now eating and sleeping better and was definitely brighter than he had been. On June 30th and July 1st and 2nd he had 40,000 units each day intramuscularly and 20,000 units on the 3rd. As he was now apparently convalescent and there were no more tetanic spasms, the chloretone and serum were discontinued. On the morning of July 1st, just a week after the first dose (4 c.cm.) of serum was injected and when a total of 173 c.cm of serum had been given by the three routes (13 c.cm. intravenously, 45·5 c.cm. intrathecally, and 114·5 c.cm. intramuscularly), the patient was very restless and complained of irritation of the back and legs, and during the day a papulo-erythematous rash appeared on the lower part of the back and on the face. The rash and irritation of the skin persisted until July 3rd, when contramine, 0·125 g. in 2 c.cm. of saline, was injected intramuscularly *twice*.

The irritation was finally overcome by the injection of 1 c.cm. of adrenalin solution (July 5th). The patient complained of pain in the left shoulder and the back of the neck for a few days (July 6th, 7th, and 8th), and of headache, but these were easily controlled by aspirin and bromides. Apart from a slight epistaxis on July 11th and 12th, the patient had an uneventful convalescence, and at no time were the joints affected. Except on one occasion—on the evening of the day that the serum was given by all three routes, when the temperature rose to 102·2° F.—the temperature never exceeded 101° F. even when the serum rash came out. There was never any difficulty with the passage of the urine, but the bowels were often difficult to move.

THE CEREBRO-SPINAL FLUID.

As is usual in tetanus, the first specimen of cerebro-spinal fluid examined was clear and normal in all respects. On June 26th, about 20 hours after the intrathecal injection of serum, the fluid which was obtained under pressure was turbid and gave a purulent sediment on centrifuging; it obviously contained several thousands of cells per c.mm.—almost all polymorphs. The albumin was 0·14 per cent. (it had been 0·02 per cent. the day before), there was good reduction of Fehling's solution, and no organisms were seen in films or obtained by culture. There was obviously a marked meningeal reaction to the injected serum but no true bacterial meningitis. On June 27th, after the second injection, the fluid was less turbid, and the cells numbered 3400 per c.mm. with 98 per cent. of polymorphs, protein 0·04 per cent., good reduction of Fehling's solution, and chlorides 7·0 g. per litre. No organisms were found in films or cultures. On June 29th the fluid was not under pressure and was clearer. The protein was 0·04 per cent., sugar was present, chlorides 7·2 g. per litre, and cells 165 per c.mm. (65 polymorphs and 100 mononuclears).

DISCUSSION.

Although it is impossible to conclude from an isolated case that antitoxin is of value in the treatment of tetanus, it was the unanimous opinion of all who saw this boy that at the time the serum treatment was begun the symptoms were advancing with alarming rapidity and that the serum appeared to check this advance and to promote recovery. Between June 24th and July 3rd no less than 633.000 units of tetanus antitoxin (B. W. and Co.) in 205·5 c.cm. of serum were administered; 40,000 units (in 13 c.cm. serum) on one occasion intra venously; 140,000 units (in 45·5 c.cm. serum) in four intrathecal injections; and 453,000 units in eleven intramuscular injections. Most authorities advise against intravenous injections of the serum on account of the risk of anaphylaxis. The Tetanus Committee of the War Office stated that the intravenous route is the most rapid method of neutralising the toxin, but dangerous on account of anaphylactic shock and "only to be recommended where the intrathecal route was impossible." In a disease like tetanus, where early and thorough treatment is of vital importance to the patient, it is permissible to take a certain risk, and in this particular instance the symptoms advanced so rapidly that the intravenous route was decided upon as being urgently necessary.

Should time permit it is advisable to give a small trial dose—e.g., 1 c.cm. of a 1/10 dilution of the serum intravenously—before giving the full dose of undiluted serum. J. W. West[3] stresses the importance of an intravenous injection of serum, in addition to the intrathecal and intramuscular injections, mentioning at the same time the danger of anaphylactic shock. He also states that the dosage should be as large as possible. Subsequent writers, such as Romanis and Mitchiner,[4] Carnegie Dickson,[5] Da Costa,[6] and Worster-Drought[7] are all against the use of serum intravenously.

The intrathecal injection of serum on several days is of the greatest value in the treatment. The meningeal reaction to the serum, the so-called "aseptic meningitis," is well shown in this as in most cases by the records of the cerebro-spinal fluid examinations, and although at first sight the turbid fluid may give the impression that a true meningitis was present, the presence of sugar in the fluid, the maintenance of the percentage of chlorides, and the absence of organisms in films and cultures all go to prove that such is not the case.

The effect of the injections of contramine in combating the symptoms of serum sickness was striking, and the use of the drug for this purpose is to be strongly recommended.

It is possible that the reason why anti-tetanus serum has not in the past been found of much value in the treatment of frank tetanus is that the dosage has been inadequate. Now that a very potent serum is commercially available, it is possible to give a patient a large number of units of antitoxin

CLINICAL AND LABORATORY NOTES

ARTIFICIAL PNEUMOTHORAX.

TWO HUNDRED CASES.

BY JAMES D. MACFIE, M.B., CH.B. GLASG.,
SENIOR RESIDENT MEDICAL OFFICER, WINSLEY SANATORIUM;
AND
ARTHUR J. P. ALEXANDER, M.D.BELF., M.R.C.P.IREL.,
ASSISTANT RESIDENT MEDICAL OFFICER, WINSLEY SANATORIUM.

THE following figures summarise the results of cases of pulmonary tuberculosis treated by artificial pneumothorax at Winsley Sanatorium during the past seven years. These results are from selected cases where an artificial pneumothorax was employed after failure of routine sanatorium treatment to effect improvement, and deal mainly with cases of moderately advanced disease. They will not, therefore, be entirely comparable with American and Continental figures, for in Canada, America, and on the Continent many more early cases are subject to collapse therapy.

Artificial Pneumothorax Attempted in 200 Cases.

	Successful induction.	Failed to induce.	Total.
Alive	94 (57 %)	12 (38 %)	106 (53 %)
Dead	72 (43 %)	22 (62 %)	94 (47 %)
	166 (83 %)	34 (17 %)	

Class.	Gain or loss in weight.*	Alive.
Of 200 cases in which A.P. was induced—		
7 were in Class 1	Gained weight 47 %; of these	77 %
53 ,, ,, 2	Lost weight 50 %; of these	21 %
40 ,, ,, 3	Remained stationary 3 %	

* These figures are based on admission and discharge figures, the average duration of residence in hospital being 6½ months.

Sputum. Before induction—
87 % of the patients were T.B. +
13 % ,, ,, ,, T.B. – or had no sputum.
On discharge—
54 % were T.B. + ; of whom 33 % are alive.
46 % ,, T.B. – or had no sputum; of whom 65 % are alive.

Period since induction.	Nos. attempted, S = Successful; F = Failed.		Number. alive.	Per cent. alive.	Number dead.	Per cent. dead.

		F 5	—	—	5	100
4 to 6 yrs...	24	S 23	7	30	10* + 6	70
		F 1	—	—	1	100
6 to 7 yrs...	6	S 5	1	20	3* + 1	83
		F 1	—	—	1	100
Total ..	200					

* In cases so marked the treatment by refills had to be discontinued. (*a*) In those alive, because of adhesions causing failure to produce satisfactory collapse. (*b*) In those who died, owing to deterioration of condition.

A certain section of the profession is still sceptical about the value of the treatment, but even if in some cases the results are not permanent yet, to use the words of the late Dr. Clive Riviere, the prolongation of life, increased comfort and wellbeing, and return of power to work—and this for the most part among cases of advanced disease—entitle the operation of pneumothorax to a very high place among successful therapeutic measures.

RAPIDLY ADVANCING TETANUS SUCCESSFULLY TREATED WITH SERUM.

BY DAVID NABARRO, M.D., F.R.C.P.LOND.,
DIRECTOR OF THE PATHOLOGICAL DEPARTMENT, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON.

AUTHORITIES are by no means unanimous as to th value of anti-tetanus serum in the treatment o tetanus after the disease has clearly declared itsel whereas the experience gained during the Great Wa showed conclusively that as a prophylactic agains tetanus the injection of antitetanic serum was ofte of considerable value. Sir David Bruce[1] in a analysis of 1000 cases of tetanus concluded th prophylactic inoculation of potential cases certain reduced the number of cases in which actual sympto developed, prolonged the incubation period, a diminished the rate of mortality in those in who symptoms did develop. It has long been recognis that the shorter the incubation period the hig is the mortality-rate, and in the cases analysed Bruce the mortality-rate was 63·4 per cent. in ca in which the incubation period was seven days less, and 54 per cent. in which the incubation per was eight to fourteen days. Golla, criticising th results, expressed the opinion that Bruce's figu showed that the question of dosage did not h at all in determining if serum had any therape effect, while C. H. Browning said that Bruce's Golla's figures would seem to show the almost u uselessness of anti-tetanus serum as a therape agent. This gloomy view was not supported, howe by Sherrington's[2] observations of experime tetanus in monkeys, in which the best results obtained by introducing the serum subdur by the lumbar or bulbar intrathecal routes.

CASE RECORD.

The following case presents several feature interest.

The patient, a boy aged 10 years, fell on a gravel on June 9th, 1931, and injured his knee. Dr. A. E. Cam of Guildford, attended to the injury, and at once cle up the wound with iodine, and inserted one suture. however, was removed next day because the wound then suppurating. Dr. Campbell and his partner, Arthur Mitchell, discussed the question of giving tetanus serum and decided against it because the boy fallen on a gravel path, which was unlikely to be inf with tetanus. A few days later Mr. E. W. Sheaf, of Guild saw the patient with Dr. Mitchell and discussed the ad bility of opening up the wound, the question of anti-te serum being again discussed and the measure de against. The temperature, which had never been h than 101° F., settled down, but began to rise aga June 24th, when stiffness of the jaw was first no Within an hour an injection of 13,000 units of anti-te serum was given intramuscularly. The wound was examined on the 24th and a small sinus which cont pus was laid open. Dr. R. C. Matson, pathologist t Royal Surrey County Hospital, examined the disc from the wound, but failed to find any evidence of te in smears or by culture. At 10 A.M. on June 25th a se dose of serum (20,000 units) was given intramusc and the boy appeared well, except that he took long his breakfast owing to the stiffness of the jaws.

Dr. Eric Pritchard and I saw the boy shortly 4 P.M. on that day, when trismus, opisthotonos, risus sardonicus were well marked, while painful sp of the abdominal muscles recurred at frequent short inte These alarming symptoms had all come on rapidly 2 P.M. on that afternoon, possibly as the result of op up the wound—which in the circumstances may seemed desirable—and thereby liberating toxins int system while there was little antitoxin present to neut although it was not a matter for grave regret if a patient with G.P.I. succumbed to treatment, the doctor felt differently about a patient suffering from gonorrhœa which seldom had a fatal termination when untreated.

The use of strong antiseptics on the vagina such as lysol, alum, and copper sulphate, might lead to a chemical vaginitis; the vagina was almost completely insensitive, or such strong preparations could never have been used. He employed diathermy in chronic gonorrhœa with arthritis, but where there was a secondary infection in the cervix he believed that better results were to be obtained by ionisation. Where the cervix was torn, severely infected, and eroded excision might be necessary; the danger of sterilising the patient need not be considered for she was usually sterile already. A pessimistic view used to be taken of gonorrhœa in the female, but nowadays, if the patient was treated early, he believed that she could be cured nearly as quickly as the male.

ACTION OF REMEDIES.

Dr. T. **ANWYL-DAVIES** said that experiments had been carried out to decide how deeply silver nitrate and picric acid solutions penetrated the cervical mucosa; it had been found that neither penetrated to a distance of more than one-sixteenth of an inch, and that they led to the formation of a tough plaque on the surface which impeded drainage. Although it was accepted that the cervix and urethra should be treated in gonorrhœa, the uterus was usually omitted. He felt sure that in a number of cases the uterine wall was infected. This explained the boggy, tender condition of the uterus so often found on bimanual examination. The organisms were too deeply embedded to be dislodged by menstruation or curettage. Although the gonococcus was easily killed in vitro at 106° F., a temperature of 112°–114° F. in the cervical canal, produced by diathermy, failed to kill the organisms, even when applied for 30 to 40 minutes twice weekly, for a period of 8 to 12 weeks; indeed, the immunity of some patients appeared to be lowered by the treatment. He believed this to be because the high local temperature was only superficial, and that a little deeper in the tissues, the optimum temperature for the incubation of gonococci was produced.

In an acute first attack of gonorrhœa the patient took between two and three weeks to develop antibodies, but in a second attack antibodies were produced within a week; this indicated that it should be possible to stimulate antibody formation if the right antigen could be found, but gonococcal vaccines, so far, had not been successful. He looked upon the complement-fixation test as analogous to the Wassermann reaction; if it was positive it indicated a gonococcal focus somewhere in the body. He regarded it also as a test of cure; if a patient in whom the test was positive was placed under treatment there came a stage, usually about six weeks later, at which the test became negative; this indicated that the gonococci had been eradicated. In his opinion protein shock lowered the resistance of the patient. The results of protein shock in gonococcal arthritis might be spectacular but he preferred to relinquish them in favour of treatment with simple antipyretics, because he knew that the ultimate cure of the patient would be retarded by shock therapy. Malaria gave a mortality of about 10 per cent. and he did not care to use this method of treatment in gonorrhœa. At the London Hospital the Wassermann reaction, the complement-fixation test, and the Kahn test were performed for each new patient, and cervical and urethral smears and cultures examined. Treatment consisted of irrigation with sodium bicarbonate, and afterwards with chloramine T. and salt; a gauze drain soaked in glycerin was then inserted into the cervix, and the vagina was packed with glycerin gauze. Patients attended daily for treatment, and came readily. After three weeks the discharge had usually disappeared and the patient felt well. At the end of each month of treatment all the preliminary tests were repeated, and when these were all normal and the complement-fixation test negative, dismissal was considered. It was impossible to distinguish clinically between a vaginal discharge due to the gonococcus and a discharge due to other organisms; laboratory confirmation was all-important. Among 200 consecutive cases, 102 had been gonococcal. Erosion had been slightly commoner in non-gonococcal than in gonococcal cases. The complement-fixation test had been positive at the first attendance in 60 of the gonorrhœal cases and negative in 42, but many of them were acute cases, and the test might take up to three weeks to become positive. In 200 consecutive cases of gonorrhœa, the gonococcus had been present in smears and cultures in 120, in smears only in 20, and in cultures only in 60. For the treatment of gonorrhœa some solution was wanted which would kill the gonococcus by autolysis, in the same way that the pneumococcus was autolysed by an intracellular enzyme. It had been found that the action of the intracellular enzyme on the pneumococcus was enhanced by sodium desoxycholate, and he had recently been employing this drug as a local application in strengths up to 1 in 200. It appeared to be effective in the early acute stage, but later glycerin drainage was more valuable.

DISCUSSION.

Dr. **LYNETTE HEMMANT** agreed that the aim must be to differentiate between acute and chronic gonorrhœa and vaginal discharges due to other causes. Laboratory tests were essential. With late, vague cases the problem was to decide whether they were the end-products of chronic gonorrhœa, and if so, whether they were still infective; and if they were not gonorrhœal, whether they should be sent elsewhere for treatment. I. N. O. Price in 1929 had described a method of recognising gonococcal colonies after 24 hours' culture; this depended on an oxidase reaction, a pink colour developing when the reagent was added. Dr. Hemmant believed that the complement-fixation test was a valuable indication of progress, waning as the case improved. She preferred to use 10 per cent. mercurochrome alternating with mercurochrome in glycerin or 2 per cent. acroflavine in glycerin. It was important to reassure and encourage patients, many of whom were despondent of cure at the outset.

Mr. **DAVID LEES** said that if the clinical picture and laboratory tests were negative it should not be assumed that gonorrhœa was absent; the examination and tests should be repeated at a time when the patient had not douched or emptied her bladder for some hours. Patients with vaginal discharge fell into three groups: those in whom the diagnosis, clinically and bacteriologically, was gonorrhœa; those in whom the clinical picture and the history suggested gonorrhœa, but who gave negative laboratory tests; those in whom there was no evidence of infection by the gonococcus, but in whom there was evidence of infection by other organisms. Patients in the third group should be sent elsewhere for treatment as it was unfair to let them bear the stigma

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

A MEETING of this section on Feb. 19th, with Mr. VICTOR BONNEY, the President, in the chair, was devoted to a discussion on

Gonorrhœa and Other Cervical Discharges.

Colonel L. W. HARRISON said that at most clinics all vaginal discharges were treated on the same lines as gonorrhœa, and no attempt was made to differentiate between them. Some attempt to make a definite diagnosis in order that treatment might be directly purposeful would be better. By means of microscopical and cultural investigation, and by the use of the complement-fixation test a definite decision could be reached. In many of his own cases, he was convinced, the gonococcus would have been missed if cultural tests had not been employed; the complement-fixation test was also valuable and gave some indication of progress. It should be possible to decide quickly whether a discharge was due to the gonococcus, to bacteria other than the gonococcus, or to chemical irritation. Cases due to chemical irritation, where douching had been employed for years, often cleared up rapidly when treated with a masterly inactivity. In cases due to bacteria other than the gonococcus the organisms were superficial and accessible, and a properly directed frontal attack sufficed to cure the condition. He was confident that a large number of vaginal discharges were wrongly diagnosed as gonococcal in origin. The use of strong antiseptic solutions for such cases only destroyed the mucous membrane and made it susceptible of invasion. The preparation chosen should be that which did least damage to the tissues when applied in a strength sufficient to destroy the organisms. He preferred to use mercurochrome in a 10 per cent. solution; this was applied to the cervix on a swab which was left in place, or changed once or twice, while the vagina was painted with the same solution. Vaginal douches alone were useless in cases where the infection was situated in the cervix.

In gonorrhœa the infection was intra- and periglandular, and a frontal attack was less likely to be successful; reliance must mainly be placed on exploiting the patients' powers of resistance. Local treatment could only neutralise the toxins and promote drainage, and if pushed too far might weaken the resistance of the tissues. Although vaccines might appear to be ineffectual if used blindly, there were a number of cases in which the gonococcus had persisted for months in spite of treatment, and where the complement-fixation test was negative or mildly positive; in these the use of a vaccine was nearly always followed by a rise in the titre of the complement-fixation reaction and the disappearance of the gonococci. In some of these cases a small dose of vaccine produced a vigorous general and focal response, and in others large doses were tolerated with little effect. He urged the importance of a wider use of vaccines in the treatment of chronic gonorrhœa. Where the use of a vaccine was found to raise the titre of the complement-fixation reaction, without an accompanying disapearance of the gonococci, glycerin drainage by the Remington Hobbs method was often useful.

INFECTION AND TREATMENT.

Mr. J. JOHNSTON ABRAHAM had attempted to decide in what proportion of cases the gonococcus could be isolated. Out of 1000 consecutive cases of vaginal discharge in adult women attending the London Lock Hospital, the gonococcus had been isolated in 411. In 437 the gonococcus was not found although the discharge was venereal in origin; the discharge was non-venereal in 152. It appeared to be more difficult to isolate the gonococcus in pregnant women. When the gonococcus was not present, cultural examination usually showed a variety of other organisms; the presence of a hæmolytic streptococcus in the cervix was a contraindication to induction or curettage. Secondary organisms tended to maintain the inflammation after the gonococcus had disappeared, and shock therapy might be useful in such cases.

It was difficult to decide on any criteria of cure. Two infallible tests could never be performed by the medical practitioner: one was the inoculation of the conjunctival sac of a baby with the discharge, and the other the inoculation of the male urethra. Nature however, performed these tests without compunction. Other tests were substitutes for these and included clinical evidence, the evidence of smears and cultures and the complement-fixation test. He did not consider that this test had any value as an indication of cure, because if the patient's antibody production was poor the test would be negative, while a vaccine could provoke a positive reaction even in a norma person. Moreover, in a patient with sealed tubes who was not contagious, the test would be positive As an indication of progress, however, the test was valuable.

Various intravenous injections, including salvarsan, mercurochrome, hexamine, and many others had been tried in the treatment of gonorrhœa he had experienced little success with intravenou remedies except S.U.P.36. Drugs by mouth had little effect; he shared Colonel Harrison's views on vaccines Pyrotherapy had recently been tried; this entailed raising the temperature of the patient to a point a which it was injurious to the gonococcus. Mill and T.A.B. injections and infection with malaria had all been employed. He deprecated the use of malarial infection in treating such patients

---

(*Continued from previous page.*)

in a relatively small volume of serum, though doubtless in hospital practice the cost of the serum rather militates against its use. The prevalent fear of injecting the serum intravenously is also perhaps a contributory cause of the unsuccessful results of serum treatment.

I should like to thank Dr. Mitchell and Dr. Pritchard for giving me the opportunity to treat and report this case; also the other practitioners and the nurses whose care contributed to the successful issue.

count must be watched, for the chief danger from the use of high-potential rays was the diminution of the red cells to the stage of anæmia. Eighteen years ago the treatment was by small doses of low potential, and some remarkably good results were secured. In one case, with whites over 700,000, the patient had to be carried into the room on a stretcher and was very dyspnœic. The treatment effected a reduction in the whites to 12,000 and the spleen returned to its normal size. To-day Dr. Russell Reynolds recommended 80-kilovolt doses filtered through 0·5 mm. of aluminium; he did not resort to higher potentials until this weaker dosage had definitely failed. In severe cases with abdominal enlargement it might be necessary to start with very small doses to avoid a dangerously acute reaction. The aim should be to obtain good results with slight penetration, the patient's own recuperative powers being kept at their best.

He had not had much experience in treating leukæmias with radium, but results seemed to be promising in a few cases where surface applications over Columbia paste had been used.

DISCUSSION.

Dr. F. HERNAMAN-JOHNSON said that occasionally an obstinate mastitis would clear up after some weeks of reaction following a somewhat high voltage application, other means having failed. In the treatment of leukæmia, his custom was to alternate X rays with ultra-violet light; this not only maintained the general health, but enabled the operator to keep his X ray dosage to the minimum.

Dr. J. H. WEBSTER said it was difficult to know which to accept of the authoritative definitions of mastitis given respectively by Mr. Sampson Handley and by Sir Lenthal Cheatle. Cases with pea-like nodules in one quadrant yielded well to X rays, though he preferred 60 kilovolts to 80. More intense mastitis with larger lumps must receive heavier doses and deeper therapy. He had obtained good results by this means in 87 per cent. of his cases. Some were later treated surgically by Mr. Sampson Handley, and some had continued pain, and finally the supervention of malignant disease. He advocated the cross-fire method where possible.

Dr. N. S. FINZI submitted that there were two distinct forms of mastitis: one a pure inflammation, the other a hyperplasia blocking the ducts. The first of these should be treated in the same way as any other inflammatory condition—i.e., with small doses of medium penetration. He used 130 kilovolts through 5 mm. of aluminium. He believed this stimulated and hastened the natural process of repair. In the other form, unless the condition was purely inflammatory, the epithelium of the ducts must be destroyed, and deep therapy was needed to ensure this. Drastic measures were required since these cases were liable to become malignant.

Dr. GILBERT SCOTT said that in the treatment of the leukæmias the chief care should be not to overdose the patient. The aim should not be to bring the white cells quite to the normal. He was convinced that each patient had his or her optimum, something between 10,000 and 12,000. By keeping down the dosage to the minimum the patient could be kept susceptible to the rays for a much longer time; in cases of relapse the rays seemed definitely less effective.

Dr. J. E. LYNHAM spoke of cases in which the breast resumed its normal size after irradiation but the pain persisted; this pain he regarded as neuralgic; it proved very stubborn. The late Dr. Robert Knox held that the effect of irradiation in blood diseases was largely on the cells in the blood stream; in susceptible cases treatment should not be pushed until the white cells were at or below normal, since the reduction would probably persist after cessation of the treatment. He thought that in course of time a scheme could be evolved by which the blood condition could be controlled during the administration of very small doses of rays. By overstepping the line in dosage it was possible to bring about a fatal result.

Dr. G. B. BATTEN said that in neuralgic congestion of breast great relief generally followed gentle rubbing towards the nipple with a mixture of equal parts of eau de Cologne and castor oil.

Recent Advances in the Treatment of Rheumatism and Asthma.

Dr. GILBERT SCOTT said that asthma and rheumatism were closely allied. It was common for a rheumatic patient to suffer from asthma and for the swelling of the joints to be a precursor of an attack of asthma. Most workers on asthma had concentrated on the thorax, but Polman, in America, had obtained improved results by irradiating the spleen. Dr. Scott believed that any benefit after treatment of the thorax was due to the accidental inclusion of the spleen in the irradiation. He was still using the method he advocated in 1926; he had devised an apparatus for the simultaneous treatment of front and back, with the object of destroying metastases from malignant foci, and a patient volunteered the information that he had cured her asthma at the same time. He covered the chest and genital organs with a layer of rubber during treatment, and used a medium wave length; full tolerance was attained when in 48 hours a feeling of slight nausea was produced. The suprarenal gland was an important factor, in his view.

Every clinic for the treatment of arthritis should, he said, have an efficient X ray department. Until knowledge concerning the best combination of wave length and filtration was more precise he did not think much progress could be expected in the treatment of rheumatic conditions. Hip-joint cases gave a quicker response to medium length rays, with aluminium filtration. By applying the rays in a certain direction a larger expanse of joint surface was reached than in any other direction. Kahlmeter claimed to have obtained good results from X rays in rheumatoid arthritis, but Dr. Scott doubted whether his patients were suffering from true rheumatoid arthritis. Such patients might get temporary relief from the rays, but they relapsed before very long. The speaker was now trying irradiation of the whole spine. The rheumatoid arthritic group showed bone changes which Dr. Scott regarded as of metabolic origin. The osteo-arthritic group of cases, if not of very long standing, were rendered symptom-free for some time. Gout he had treated only in the acute form by irradiation, which brought great relief. Cases of spondylitis deformans were among the major tragedies of medicine; patients afflicted between 20 and 30 years of age were old before they had had a chance of anything like a full life. In 90 per cent. of them infection was present, the sacro-iliac joint being usually the earliest affected. It might be wise to ask the orthopædic surgeon, in the early stage of the condition, to curette that joint. There was not much hope of cure if the condition had existed more than two years. In both active gout and acute gonorrhœa medium length X rays gave rapid relief.

of attending a venereal diseases department. The primary principles of treatment in gonorrhœa were physical and mental rest, and attention to general hygiene. If all acute cases could be admitted to hospital until after the next menstrual period the incidence of tubal infections, he believed, would be cut down by 75 per cent. In treating urethral infections he preferred to use permanganate of potash or albargin which promoted mild venous congestion and improved drainage. Strong antiseptics might do damage; for urethral treatment he would not use mercurochrome in a stronger solution than 2 per cent. For the cervix he used picric acid, and thought it extremely important, after swabbing, to dry the vagina with magnesium oxide or starch. Chronic cases he *treated by glycerin drainage and by* dilatation and cervical suction or urethral suction. He had obtained good results with electrargol in Bartholin infections; 1 to 2 c.cm. were left in the abscess cavity, but if this failed the gland could be excised. He had only found bacteriophage valuable in ophthalmia neonatorum, which usually cleared up after two applications. Diathermy he used as an adjunct, not a cure. Every case could be cured in time, and a reasonably optimistic attitude should be encouraged in the patient. If all tests were clear at the end of three months the patient might be given a provisional clean sheet. At the end of six months the *tests should be repeated after a provocative dose* of vaccine and the insertion of glycerin drains in the cervix and urethra. If the tests were still negative the cure might be regarded as established. In many pregnant cases it was impossible to demonstrate the gonococcus, but the patient should be treated even if the tests were negative, only mild antiseptics being used. It had been found that in the cases so treated the puerperia were less morbid than in clean cases.

Mr. D. H. MacLeod said that at the Middlesex Hospital it was found that one-fifth of the total number of patients ceased to attend before they were cured. The *average duration of treatment* in non-gonococcal cases discharged as cured was 12 months and in gonococcal cases 15 months. If, on the examination of a smear, no gonococci were found and the pus cells numbered less than 50 per cent. of the total cell count, a negative result was reported. He had obtained little success with vaccines.

Dr. J. C. Moir had used diathermy in 44 cases where the gonococcus had persisted in spite of previous local treatment. After six treatments 20 were clinically cured and gave three negative monthly smears. He believed that diathermy had no direct effect on the organisms, but acted merely by causing vascular dilatation and promoting drainage. In acute cases diathermy was useless and only aggravated the discharge. He referred to a condition in which there was a sudden appearance of an irritating discharge associated with vaginitis but no urethritis; the gonococcus was not found but the *Trichomonas vaginalis* was constantly reported and might be the causal organism.

Dr. D. Watson advocated the use of tubular sounds when exploring the cervix or urethra; there was less chance of pushing infected material into the uterus or bladder than with a solid instrument.

Dr. Muriel Keyes described the spectacular cure of a case of severe gonococcal arthritis by means of pelvic diathermy. The patient relapsed or was reinfected, and a second attack of arthritis was cured in the same way.

Miss D. C. Logan mentioned the use of alkalis in the treatment of discharge due to an acid secretion associated with the *ordinary group* organisms. She emphasised the value of glycerin drainage in gonorrhœa.

Colonel Harrison, in replying, said that antenatal *treatment of pregnant* women was important from the point of view of the obstetrician; the descent of the infant was analogous to the passage of a catheter through a dirty urethra, and he advised a thorough *local toilet of the patient at the* beginning of labour.

SECTION OF RADIOLOGY.

A meeting of this section was held on Feb. 19th, with Prof. J. M. Woodburn Morison, the President, in the chair.

Dr. Russell Reynolds opened a discussion on

X Ray Treatment of Mastitis and Certain Leukæmias.

He said he used the term "mastitis" in the same sense as did Mr. Sampson Handley in his Bradshaw lecture.[1] Several types of case presented themselves for treatment. In early chronic cases increased cellularity, and more acini than usual, were to be seen, while enlarged ducts formed irregular projections into the lumen. In more advanced cases the *elastic tissue of the smaller ducts* disappeared and the acini were surrounded by a wavy fibrous tissue, which came to a point at the nipple. The part of the breast most affected was the outer and upper quadrant. The condition might follow a preceding acute mastitis or trauma, or irritation caused by pressure of the clothes. These cases yielded readily to small doses of X rays at a low potential, 80 kilovolts. In a general way he ha found a suitable dosage *to be half an erythema* dos of unfiltered rays, three such doses at weekly interval usually sufficing. In most cases there was no retraction of the nipple, but patients complained of aching *and of a shooting pain in the* breast, sometime passing up the axilla. Tenderness might be acut and a soft axillary gland might be palpable. Durin the first few hours following the treatment increase fullness and discomfort occurred, but after 48 hou that had usually passed off, and in seven days th mastitis had definitely improved. After the secon and third dose the discomforts diminished. Som times it was well to delay subsequent doses if th *reaction had been pronounced. One type* of mastit was met with at the climacteric, both breasts bein equally affected. These cases did not respond s readily to treatment, and if the mild treatment di not succeed, two or three doses of shorter wav length should be substituted. In some chron cases cysts formed, these being due to dilatation the ducts in the lobules of the breast tissue, and i the cysts papillomata might occur. The induratio *disappeared before the cysts*, but these were oft dissolved by 130-kilovolt doses; they might nee deep X ray therapy. In his view mild X ray trea ment of mastitis might act as a prophylactic measu against a later development of carcinoma.

As to the treatment of leukæmias, Dr. Russe Reynolds said that the nature of leukæmia was n yet clear; but X rays and radium had a profoun effect on the condition, irradiation being, in fac the *most* effective weapon available. His lon experience had convinced him, however, that th treatment was no more than palliative; the bloo rather than to his words; Dr. Adler would agree with much that had been said. Dr. Young's assumption that people think that society is infallible was not a gospel to-day. When an individual antagonised society, and refused to coöperate, he was only expressing a decision to make his own terms or break with society. The underdog was not always a hero. Dr. Crichton-Miller did not agree that Dr. Adler stood for a static society, he did not deserve the metaphysical pounding he had just received.

---

[1] The Lancet, 1931, ii., 1169.

Dr. C. I. Schiff remarked that the original basis of individual psychology was the question of inferiority not coöperation. Coöperation arose as a means of curing the inferiority. Adlerian psychology owed its birth to the influence of Nietzsche. A neurotic was a person who could not fit into any society.

Dr. T. Lawson doubted whether adaptation and coöperation were the same thing; Dr. Adler spoke more of adaptation. If parents understood their children, the children would be able to adapt with more courage.

Dr. Hilda Weber pointed out that the society to which Dr. Young had referred was rather vague and indefinite. Coöperation was to a greater extent concerned with something more tangible—i.e., real, living people; Dr. Adler's injunction, "to do something for somebody else" was appropriate here. Even those who retired from society, for instance the monks, coöperated very definitely with a well-defined society within the monastery walls. She referred to the bonds which united the members of the different schools of psychology.

Dr. F. Bodman said that the question of adaptation in connexion with the individual was largely one concerned with the milieu in which he lived.

Dr. J. D. Hessey thought that the previous speakers had taken too parochial a view of society. Adaptation to a section of people was one thing, and adaptation or coöperation with society as a whole another. He considered that the present chaotic condition of society could only be changed by integration of the individual according to the principles of individual psychology.

Dr. G. Gordon remarked that it is not always wise to deal with patients philosophically. Society had its rights.

Dr. M. Marcus said that every doctor should have his opinion as to what constitutes a good society, and what are the elements with which the individual should coöperate.

Dr. Bevan Brown held that the neurotic was one who did not *want* to coöperate. He should be freed from his conflict so that he could coöperate.

Dr. A. Sanderson said that Dr. Young had crystallised the difficulties which he himself had found, Adler seemed to plead for the world as it is.

Dr. Burnett Rae considered that the psychologist who is out to help must have an individual point of view; he must have something to give to the patient.

Dr. F. G. Crookshank contended that Dr. Young spoke more against words than content. It was a valuable destructive analysis of a false interpretation of coöperation. The neurotic was one who has no real social feeling. His purpose was aggrandisement rather than coöperation. It was not necessary to assume that change is always good. Adler pointed out that criminals do coöperate, hence the saying, "honour among thieves"; the criminal was a product of society. Adler did not suggest that the small group should necessarily agree with the larger. In urging coöperation he meant willingness to conform so far as was consistent with the good of the larger whole. Keats contributed to art, but he did not coöperate with others in life. Adler would probably say that the question to be considered is whether it is better to have a fairly uniform and happy society with fewer works of art.

REPLY.

Dr. J. Young said that he had not been tilting against Adler's spirit. He had been speaking of the philosophic background. It was necessary that this should be made conscious and be understood, otherwise every kind of malpractice might be allowed in the name of individual psychology. He considered that organ inferiority, emphasised by medical men, was inseparable from adaptation. He agreed that all the onus should not be put on to society; nevertheless the responsibility of parents was often insufficiently recognised. By society he meant the inertia of life, the drift of things.

LIVERPOOL MEDICAL INSTITUTION.

A meeting of this institution was held on Feb. 4th, with Prof. R. E. Kelly, the President, in the chair.

Antenatal Radiology.

Dr. R. E. Roberts read a paper based on the results of radiography in 550 cases, all of which presented some element of clinical doubt or difficulty. The method was useful, he showed, in estimating the exact degree of pelvic deformity and the position and size of the presenting part in relation to the normal pelvis. It was also of value in estimating the maturity of the fœtus at any time after the end of the fourth month—especially in cases where the clinical evidence was doubtful. Further, it gave important information not only about the presentation but also about the position of the fœtal limbs in relation to the trunk and head, and in cases of multiple pregnancy it demonstrated the relative positions of the fœtuses. Cases of extra-uterine pregnancy were difficult to diagnose unless some means could be adopted of more clearly visualising the position and size of the uterus. In deciding the cause of hydramnios, radiography was found to be invaluable; fœtal abnormalities were, as a rule, diagnosed with precision where their nature or even presence was uncertain from clinical examination.

Prof. W. Blair Bell said that he had coöperated with Dr. Roberts from the commencement of his work on antenatal radiological diagnosis and great benefits had accrued to his patients thereby. Yet he had found great difficulty in persuading some of his colleagues in other places that it was possible accurately to measure the pelvis, estimate the age of the fœtus, and so on. There were still those who were regarded as authorities on antenatal work, but did not yet recognise the fact that radiography was, in many cases, an essential part of antenatal investigation; the most they would admit was that this was a matter for further research! Estimations of the age of the fœtus and of the hardness of the skull were of great value, for postmaturity was not uncommon, and often led to difficult labour from disproportion if the head would not mould in the normal manner. On the evidence of a radiogram, induction could be practised in good time. Actual measurement of the head, which was difficult, was in reality not of any special value, for a slight degree of hydrocephalus was

The real value of X rays in rheumatism was not yet known, and careful observations of the results of various doses were needed. Sometimes obstinate cases yielded to a change of dosage. So large did cancer loom in the X ray departments of hospitals that less serious conditions took a secondary place. The idea that the maximum dose of rays would produce the maximum benefit was no more true than it was of drugs. He looked forward to the time when a sort of X ray pharmacopœia would be available so that the practitioner could readily ascertain what was the best dosage for a particular disease.

The PRESIDENT said that he had started treating asthma by X rays many years ago in Manchester. At first he treated the lungs, later the spleen, and finally he concluded that the result did not vary much with the part to which the rays were directed. The type of patient who derived benefit from X rays yielded also to ordinary protein shock methods. He agreed that the rays should not be applied to the chest in cases of asthma.

Dr. S. L. MUCKLOW said that in one group of asthma cases X rays cleared up the condition, and there was no recurrence for one to two years. In another group the patient remained free for nine months without recurrence, and subsequent attacks were reported to be milder. In a third kind of case recurrence took place three months after the temporary cure.

Dr. W. F. COKE said that the differentiation of those types of asthma which yielded good results when X rayed was urgently required. In his view the change brought about was a biochemical one.

Dr. WEBSTER remarked that other spasmodic conditions also benefited from X rays, especially pylorospasm and other gastro-intestinal states. When the whole body was treated it should not be by deep therapy.

Dr. HERNAMAN-JOHNSON said that the early medical treatment of Graves's disease should certainly include X rays, before the case was handed over to the surgeon. Small doses of X rays two or three times a week would often result in increase of weight and lowering of the pulse-rate.

MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY.

AT a meeting of the society, held on Feb. 11th, at 11, Chandos-street, with Dr. F. G. CROOKSHANK in the chair, Dr. J. C. YOUNG read a paper entitled

Individual Psychology and its Philosophical Implications.

Dr. Young indicated in outline the practical importance of a clear understanding of the philosophical implications of individual psychology. He then dealt in more detail with the theses as enunciated in a lecture, entitled "The Meaning of Life," in which Dr. Adler develops the view that the meaning of life is to be found in contribution and coöperation. Dr. Young criticised this conception on the grounds that, valuable as it is, it involves certain inherent contradictions which cannot be resolved in terms of individual psychology as at present formulated. The wide conception of "contribution"—Adler exemplifies this concept by work, children, ideas, and so on—requires qualification. Work may be good or bad, children healthy or sickly, ideas true or false—in other words a contribution may be positive or negative. The feature common to all positive contributions is their survival value. But even this position requires further consideration. Just as that which is useful at one period of life may later be outgrown, so the genuinely positive contribution may in time become negative. In addition the positive contribution in one order of life may be based upon a negative contribution in another. Some of the most painful cases of maladaptation occur in those whose positive contributions are infinitely greater than are some of those whose social adaptation is apparently complete. The poetical works of Keats are enduring, yet the man himself was not socially well adapted.

It was not sufficient therefore to say "adapt yourself to society"; such a formulation of social coöperation is inadequate and a danger. One must be certain of the intrinsic value of society before one is justified in urging the sacrifice which such adaptation involves. The point at issue was whether the society with which the individual should coöperate should be that of the past or of the future, that of the present being a flux between the two. The medical psychologist must have a clear conception of the order of society required to resolve the contradictions of patients of high potential value. Such a society must be living, dynamic, biological, not static and mechanical, otherwise there was danger that one might be pressing for coöperation with an obsolete society, for adaptation which is bad. There was a creative-destructive urge in life which constantly presses not only towards the creation o something new, but also towards the destruction o what is obsolete, so that the new may emerge Society as a living organism must be prepared fo creative convulsions similar to those which occu in the animal organism, for instance the mino convulsion of the moulting bird, or the majo convulsions of man at puberty. The increase i number and complexity of psychological problem suggested that a great social convulsion, initiated b the Great War, is now in progress. It was not merel the individual who has reached his capacity t coöperate; the onus must at times be shifted on t society. The doctor now dealt with psychologica difficulties formerly taken over by the priest. He migh not be able to offer to the psychologically recalc trant the consolations offered by religion, but h could point out that one way of coöperating with society of the future was by helping to bring about on which would be more completely coöperative. Ma must no longer be regarded dualistically as consistin of the natural and the supernatural, but as a dynami and organic whole. Not the "organic" of medica tradition, but one which was totally inclusive of th human being. Existing society must not be accepte as finality, a norm. Adler had said "the crimin will not coöperate." But to the extent that it doe not bow to the established order of things the rev lutionary spirit might be regarded in the same wa It was important therefore to distinguish betwee positive maladaptation and negative maladaptatio between the forward-looking "revolutionary" an the backward-looking "criminal." Inability t coöperate with existing society might denote capacit to coöperate with a future society which is deni expression by society as at present constituted.

DISCUSSION.

Dr. H. CRICHTON-MILLER said that there wer several fallacies underlying Dr. Young's thesis It was a good motto to speak to a man's meanin

REVIEWS AND NOTICES OF BOOKS

A Text-book of X Ray Therapeutics.

Fourth edition. By ROBERT KNOX, M.D., M.I.E.E., D.M.R.E. Completed and edited by WALTER M. LEVITT, M.B. Irel., M.R.C.P. Lond., D.M.R.E., Medical Officer in charge of the Radiotherapeutic Research Department and Assistant Medical Officer to the X Ray Department, St. Bartholomew's Hospital, London. London: A. and C. Black, Ltd. 1932. Pp. 250. 21s.

TWELVE years ago the late Dr. Knox published a volume on radiotherapeutics that covered the application of both X rays and radium to medicine. When he died in 1928 he had for some time been at work on a similar book which would deal only with X ray therapy. Dr. Levitt has taken up the tale where Dr. Knox left it. He had not had the opportunity of working with Dr. Knox and it was a bold step to take over his material, and, after four years during which X ray therapy has made feverish progress, to attempt to weave it into a connected whole. Dr. Levitt has justified his courage for he has produced a valuable work, and has, moreover, helped to perpetuate the memory of a pioneer who in the very earliest days strove to help radiotherapy out of the stage of empiricism and place it on a scientific plane. It is interesting to compare this volume with its predecessor, written at a time when dosage was entirely empiric. Extraordinary advances have taken place in the power of the apparatus available, in its reliability, and more especially in the measurement of the intensity of radiations at any required depth. A welcome appendix is a paper by Dr. Knox read just before his death at the Stockholm Congress, in which he discusses the biological factor as a guide to dosage and its influence upon developments of technique.

Dr. Levitt has succeeded in fusing his own material with that of Dr. Knox, and has contrived to make the book an almost continuous story. Of the many excellent chapters, we would particularly commend the balanced and judicious accounts of the effects of X rays on tissue. The chapters on physics, X ray measurement, and filters are admirable; it is perhaps unfortunate that the account of principles of X ray therapeutic technique does not follow these chapters directly, being separated from them by two chapters dealing with apparatus. The technique of the treatment of malignant disease in different regions is described in a simple, straightforward way, and where a variation of method is advised a satisfactory reason for it is usually supplied. It is interesting to compare these chapters with those in Dr. Knox's original book. The conclusion reached from such a comparison is that X ray therapy of deep-seated lesions has made great strides in the last twelve years, while the treatment of superficial lesions, if judged by this book alone, would appear to be at a standstill, for the chapters in the two books are, for the most part, identical.

This treatise will be a reliable guide to the experienced medical radiologist to whom alone X ray therapy should be entrusted. It will also serve as an indication to physicians and surgeons the present scope of X ray therapeutics. There seems to be little doubt that in the future this scope is likely to be enlarged, especially as a supplement to treatment with radium.

Annals of Roentgenology.

A Series of Monographic Atlases. Edited by JAMES T. CASE, M.D., Professor of Roentgenology, Northwestern University Medical College, Chicago. Vol. XIII. *Gynæcological Roentgenology.* By JULIUS JARCHO, M.D., F.A.C.S., Sydenham Hospital, New York. New York: Paul B. Hoeber, Inc. 1931. Pp. 571. $20.00.

THIS volume, devoted to gynæcological radiology, is almost entirely concerned with X ray diagnosis. The one chapter dealing with radiotherapy gives such a very brief survey of the subject that it is of little value to any but the most general reader.

In the first few chapters Dr. Jarcho gives a clear and detailed description of the technique for producing a pneumo-peritoneum designed to aid radiography of the pelvis. He points out the various uses that can be made of X rays in gynæcology, and goes on to enumerate the complications which may occur, and have occurred, during the production of pneumoperitoneum. Next he discusses the value of insufflation of the uterus and Fallopian tubes as a means of diagnosing the patency of the latter, and again draws attention to the possible dangers if too great a pressure is used. As an alternative, the method of injecting iodised oil through the uterus and tubes is discussed at length, and very precise details are given of the technique. The author himself uses and recommends a combination of induced pneumoperitoneum and utero-salpingography, which he believes gives a clearer picture of any abnormalities that may be present than either method alone. He quotes some cases in which dysmenorrhœa seemed to be cured by insufflation of the tubes; it is probable that these cases were really of the congestive type.

The diagnostic part of the volume should prove of great value as a book of reference and as a practical guide in the various methods of utero-salpingography. The section on radiation therapy gives some useful references to the work of various authorities but is not of the same practical value as the rest of the book. Every gynæcologist will agree with the author that radiotherapeutic abortion by means of X rays is not justifiable; but surely in order to emphasise this it is not necessary in a book on radiology to give a detailed description of how the author produces abortion by mechanical methods. Finally, there is appended a very full bibliography and carefully compiled subject index.

Menschliche Auslese und Rassenhygiene.

Third edition. By Dr. FRITZ LENZ, Professor der Rassenhygiene an der Universität, München. Munich: J. F. Lehmanns. 1931. Pp. 594. Mk.17.

THERE have been considerable changes in this work since the first edition ten years ago; it now appears as a text-book of eugenics in the widest sense, and includes also a good deal of politics and sociology.

The first part deals with selection in man, especially biological influences, and the part played by acute infectious diseases, tuberculosis, venereal disease, infantile maladies, alcohol, and war. A study of the effect of selection upon the efficiency in modern life of the various systems of the human body is followed by rather controversial sections on social and racial factors in selection, with a thorough examination of diagnosed by the radiographic appearance rather than by the size of the head.

Prof. H. **Leith Murray**, while deprecating any substitution of radiography for careful palpation, said he had found it of extreme use in difficult cases. In many of these the patient was so fat that palpation was far from easy. No obstetrician should ever allow a case to enter labour without a full diagnosis of the presentation and the position having been made. Without the assistance of radiography this could not be guaranteed in all cases. Lack of flexion, too, might suggest a disproportion which was not, in fact, present. Here, also, modern radiology could be of great service in cases where palpation was inconclusive. With regard to the diagnosis of degrees of immaturity, while he had found radiography reasonably useful in cases with an undetermined amenorrhœa and a fat abdomen, he would require a longer series of cases than had been presented by Dr. Roberts before he agreed that radiography was superior to a study of the abdomen and the duration of amenorrhœa.

Dr. R. M. B. **MacKenna** read a note on Three Unusual Lesions of the Scalp.

At a pathological meeting held on Feb. 11th, the Vice-President, Mr. **Frank Jeans**, being in the chair, Prof. C. E. **Walker** read a paper on

Some Aspects of Cancer.

Prof. Walker said that a case of cancer might go through periods of improvement and regression. Very rarely there might be a spontaneous cure, and this seemed to be brought about by an overgrowth of fibrous tissue which destroyed the cancer cells. Connective tissue had been neglected by cytologists; the more delicate cell phenomena were not visible in ordinary histological and pathological specimens. Yet the connective tissue cells must multiply and differentiate freely and frequently. Any destruction of a tissue beyond a very small amount was replaced, not by the multiplication of the cells of the injured tissue, but by connective tissue forming a scar. There was a tendency for leucocytes to crowd round the advancing edges of malignant growths. Connective tissue and blood were closely related in their development. At some stages it was impossible to say whether a particular cell was going to become connective tissue, or the ancestor of a leucocyte. This close relationship continued throughout life. There was an insensible gradation between the wandering connective tissue cells and leucocytes. It was possible that the temporary improvement in some cancer cases was due to the leucocyte activity in the production of connective tissue having caught up and temporarily counterbalanced the multiplication of the cancer cells. It was probable that the reaction which followed many of the methods of treatment described was brought about in the same way. The result might be purely mechanical. Experiments seemed to show that cancer cells were more resistant to unfavourable factors in the environment than were the corresponding normal tissue cells. Therefore it might well be more profitable to seek some methods of stimulating the wandering cells that accumulate round a growth than to attempt to find something that would kill the cancer cells without killing the patient.

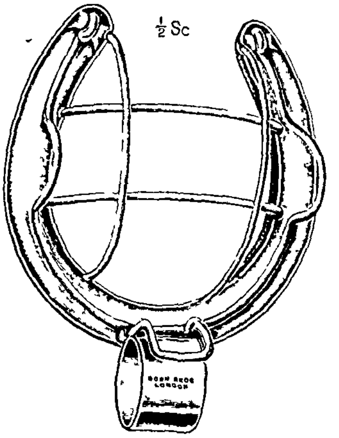
In the speaker's opinion, many of the methods of treatment described did have this affect to a partial extent, and it would probably be better to aim directly and deliberately at obtaining this result, and assist the wandering cells and their offspring in what appeared to be their function.

NEW INVENTIONS

AN ANÆSTHETIC MASK FOR OPHTHALMIC USE.

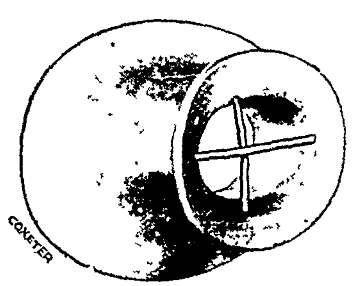
The mask here illustrated consists of a hemispherical wire dome on a horseshoe-shaped gutter. There is no bridge of wire at the nasal end. In practice, any mask which straddles the nose is in the surgeon's way, particularly during operations in the lower lid and lacrymal sac regions. The mask invariably gets pushed off the nose, allowing too great an air leak. This mask rests just at the end of the nose. The gap between the ends of the horseshoe gutter is bridged by the lint, which is intended to be worked up with the finger into a hood. This hood covers closely the lowest half-inch or so of the nose, and can be accommodated to any average-sized nose by merely working up with the finger, or pulling on the lint at the sides. The mouth and nostrils are thus closely covered, while the mask is as far away from the operator as possible. Other useful features are loops in the clamping wire, at the sides, to allow of the passage under the lint of a tube from the oxygen cylinder or Junker's bottle. The idea is that of Shipway's mask, but the soldered-i metal tubes were not thought necessary, as a medium sized rubber tube is clamped quite tightly enough t prevent accidental falling away, and a ring handle modified from Dunderdale's, is fixed to the chin en of the gutter. The makers are Messrs Down Brothers Ltd., London, S.E.

R. **Burns**, M.B.



A NEW ORAL PROP.

At the present time many operations not demand ing complete relaxation are performed under pu nitrous oxide-oxygen anæsthesia. In most cases th use of an artificial airway is neither practicable no necessary. In certain circumstances, however, such as nasal obstruction, the employment of an oral prop facilitates a smooth anæsthesia. Most of the available props have been designed for use in dental surgery, and are consequently unsuitable. The one illustrated is curved to conform to the shape of the front of the jaws, and is practically self-retaining. The posterior aperture is provided with cross wires to prevent occlusion by the tongue, while the anterior aperture is sufficiently wide to keep back the lips without getting in the way of a face-piece. The biting surfaces are covered with sheet lead to protect the dental enamel, and the whole is chromium plated.



It has been made to my design by Messrs. Coxeter.

London, N.W. C. **Langton Hewer**, M.B., B.S. Lond.

Reminders and Suggestions

For the
Treatment of
INFLUENZA, PNEUMONIA,
COUGHS, COLDS, BRONCHITIS, etc.

KINECTINE An organic arsenical salt of Quinine indicated in Influenza, Acute Coryza, etc.

Tubes of 10 Tablets: Dose—One three times a day.

CRYOGENINE (Lumière) A particularly safe and reliable analgesic and antipyretic in all febrile conditions. Bronchitis, Pneumonia, Influenza, Pleurisy

Powder and Tablets: Dose—From 0·50 to 2·50 gm. daily as required.

ORARGOL An electrically prepared Gold-Silver Colloid for general antisepsis and effective colloidotherapy.

Ampoules of 5 c.c. and 10 c.c.

By intravenous or intramuscular injection Orargol is capable of aborting serious cases of Influenza and Pneumonia, and exerts an antitoxin-like effect in acute infectious conditions.

Also supplied in special O.R.L. Outfit for Nasal Irrigation in the treatment of Rhinitis, Tonsillitis and Naso-pharyngeal inflammations.

Extremely valuable as a prophylactic against Colds and Influenza.

SYRUP CREOSAL (Dubois) A combination of Guaiacol, Calcium and Phosphoric Acid pleasantly flavoured with Syrup of Orange Flower & Cherry Laurel.

An excellent specific for Coughs—whatever their origin—Bronchitis, Laryngitis, and all Catarrhal Conditions.

SYRUP PERTUSSIS (Gabail) A combination of deodorised Valerianate, expectorants and sedatives presented in a palatable form with Syr. of Raspberry.

An effective medicament for the Paroxysms of Whooping Cough.

LITERATURE AND SAMPLES ON REQUEST FROM

The Anglo-French Drug Co., Ltd.,
238a, Gray's Inn Road, LONDON, W.C.1.

the data bearing on growth and quality of population. From a brief account of migration, both within the nation and abroad, Dr. Lenz passes on to consider the future of the great racial groups; his speculations are coloured by his predominant concern about the fate of the Nordic peoples.

The second part of the book is devoted to practical eugenics. Legislative control of marriage and measures for preventing or advising against undesirable procreation are discussed as they concern society in general, and as they determine the private life of the individual and the family. Here, too, the author's nationalist preoccupations loom large. The field of racial hygiene is covered in this large book with great, if biased thoroughness, and the personal attitude of the author is never in doubt; so much so that in many places the book reads more like a manifesto than a treatise. Learned, sincere, but often partisan and intemperate in its zeal, it cannot be regarded as a satisfactory exposition of eugenic doctrine, as understood in this country at any rate, though it is excellent in its presentation of the great range of eugenic problems and their paramount importance for occidental nations.

A Manual of General Practice.

Second edition. By W. STANLEY SYKES, M.A., M.B. Camb., D.P.H. London: H. K. Lewis and Co., Ltd. 1931. Pp. 213. 7*s.* 6*d.*

THIS useful book, of which a second edition has now appeared, fulfils a definite purpose in describing the sides of general practice which are not often considered by newly qualified men. Many valuable hints and facts are given on such varied subjects as the start in practice, conduct of practice, treatment, certificates, dispensing and drugs, book-keeping, lists of necessary instruments, and the working of the national health insurance. The chapter on the diseases of general practice is perhaps the least satisfactory. It is a book that should find its way into the library of every medical school, and will doubtless be purchased by many who read it there to their great advantage. With the help of such a book as this the start in practice becomes considerably simplified.

The Neural Energy Constant.

A Study of the Bases of Consciousness. By JOHN BOSTOCK, M.B., D.P.M., Honorary Neurologist, Brisbane General Hospital. London: George Allen and Unwin, Ltd. 1931. Pp. 178. 6*s.*

THE object of this essay is to bring forward a neural theory of human behaviour; it belongs entirely to behaviourism and does not bow the knee to any psychological theory, although the presiding deity is, in the author's regard, the faculty of awareness which is a suspiciously psychological concept. Primitive consciousness is pure awareness and its guiding motive is the urge to adjustment. Awareness and emotion are localised in the optic thalamus. This is the mechanism for coarse adjustment to environment, whereas fine adjustment is implemented by the cerebral cortex. There is a constant of neural energy and in any act of adjustment a minimum number of neurones is operative. The theory of neural energy, in Dr. Bostock's estimation, explains inhibition and sleep on the basis of an activity akin to McDougall's theory of drainage. While energy remains constant, it is repeatedly passing from one minimal neural set to another in order that accurate adjustment to environment should be possible. Sleep is a dissociation of the centres of awareness, emotion, and fine adjustment, and the author feels that dreams can be classified on the basis of such dissociation, and that they do not call for a theory of the unconscious, which to him means a brain within a brain. The thesis is distinctly a diagrammatic one, and on the basis of neural function it gives a reasonable picture of behaviour in terms of nerve structure. In our view Dr. Bostock places too much reliance upon the fiction of localisation, which the work of C. S. Lashley in recent years has somewhat invalidated. The frequent inclusion of psychological terms in what is a purely neurological explanation shows that we are still far from an adequate mechanical explanation of behaviour in terms of the nervous system. When behaviourists suffer the inclusion of psychological terms, it would appear that after all psychology is not without its uses, and perhaps that the study of the organism as a whole will profit if it pursues its course in psychological terms, leaving the neurologists to translate behaviour into the language of neurones. Dr. Bostock evidently does not feel it necessary to examine the concept of neural energy, which other neurologists find unsatisfactory.

History of Scottish Medicine.

Second edition. By JOHN D. COMRIE, B.Sc., M.D London: Baillière, Tindall and Cox. 1932. 2 vols Pp. 852. With 2 plates and 404 figs. in text. £2 10s

THESE two handsome volumes, compiled by the University lecturer on medical history at Edinburgh owe their inspiration to Sir Henry Wellcome, and are issued by the publishers for the Wellcome Historical Medical Museum. Dr. Comrie is well known as a master of medical history, and has held his chair at Edinburgh for more than 20 years with distinction. He covers fairly the whole range o his subject as illustrated by Scottish events and ha produced a work of interest to archæologists, biographers, and doctors alike. The first chapter deal with medical folk-lore—Gaelic manuscripts hereditary families of doctors, charms, spells, and amulets; thence we pass to the consideration o early public health measures against leprosy, syphilis and plague; the "Seal of Cause," the charte granted by King James IV. in 1505 to the Guild o Barbers and Surgeons at Edinburgh is reproduced in facsimile, and the origins of the Royal Corporation are set out. The second volume starts with th story of military medical practice in the eighteenth century in Scotland, and gives the interesting biographies of Pringle and Prince Charlie's famou doctor Sir Stuart Threipland. The personalities which have distinguished the Edinburgh Medical School then come in for full reference, the period o the great teachers, the Monros, the Bells, Syme Liston, and Simpson being dealt with in detail Further chapters are devoted to the rise of the medical schools of St. Andrew's, Aberdeen, and Glasgow, and, both topically and pictorially, every aid is given throughout by free illustration.

These volumes are an expansion of a book o the same subject written five years ago on the occasion of the inauguration of the section of medical histor at the meeting in Edinburgh of the British Medica Association, and certain of the material has also appeared in the *Edinburgh Medical Journal* and the *British Medical Journal*. The work will be esteemed in all medical libraries as a beautifully produced and convenient source of reference.

THE LANCET.

NDON: SATURDAY, FEBRUARY 27, 1932.

RADIUM AND THE PUBLIC.

HE fragmentation of the four-gramme bomb adium lent to the Westminster Hospital has accompanied in the daily press by an explosion se loudness is disproportionate but understand-. On the KING's recovery from illness much ey was spent on the purchase of radium great hopes were founded on the immediate ng of lives to be effected by the provision the ability to use a prodigious supply of a and potent remedy. Any setback in the very of the goods was bound to cause acute ppointment, and the letter over six medical es in the *Times* of Feb. 9th, containing a test against the decision of the National Radium mission to withdraw the bomb, released this espread feeling of disappointment and led to hasty expression of doubt whether those to m the radium was entrusted were acting wisely. one questioned the motives of the Commission, there has been sharp criticism of its judgment. letter in the *Times* stated categorically that ain types of cancer are better treated by the nb than by any other method of using radium, equally categorically that surgical operations being done in this country which are no longer ifiable in view of the possibilities held out by iological treatment.

Ve need not set out here the arduous work of Radium Commission in developing radium tres in various parts of the country, and in bining the Mount Vernon Hospital and the dium Institute into a post-graduate radium ool; but it may be well briefly to recapitulate at led to the decision to entrust so large a mass radium—one-sixth of the whole stock—to a ticular institution for a particular purpose. e Radium Subcommittee of the Committee of il Research, whose report preceded the appointnt of Radium Trustees and of the Radium mmission, remarked on the inadequacy of our sent knowledge to decide whether radium is st applied at close quarters to malignant growths thin the body or whether the future lies rather th massive doses of penetrating rays applied at listance. Some of the most far-seeing of radium rkers at that time regarded the logical development of contemporary knowledge to be the use large quantities of radium at a distance from the dy, enabling a wide field to be covered and a rly homogeneous intensity of irradiation to be ven at a moderate depth below the surface. was to give effect to this view that one of the st acts of the Radium Commission was the rchase of a four-gramme bomb of radium in der to try out a method of treatment which had been used for some time previous in Paris and Stockholm. The results obtained abroad were, in the Commission's judgment, "undetermined" and the experience gained not sufficiently encouraging to justify the acquisition at that time of more than a single such bomb of radium. In their first annual report, and indeed in every report which the Commission has issued, it has never failed to emphasize the fact that at present radium is a very dangerous weapon and one which, unless used with the greatest skill, care, and precaution, may easily be productive of more harm than good. A year later it was represented to the Commission by medical representatives of the institution that the results so far obtained with the bomb were of such a nature that they did not wish to continue work with it unless divided up into smaller units. Acting on this report the Commission decided that the continued use of the bomb in its present form was uneconomic. No doubt the test had been a very severe one for any form of treatment inasmuch as, in two of the regions chosen surface therapy with radium had already proved inefficacious. It would be idle for anyone to criticise the wisdom of the Commission's decision without seeing the actual protocols of cases treated, but it may be recalled that at the International Congress of Radiology, held last July, REGAUD and MONOD admitted that 17 out of the 19 cases of carcinoma of the stomach treated with the bomb at the Radium Institute in Paris during the years 1925–29 were already dead; and only one of seven cases of carcinoma of the bladder treated from 1927–29 was still alive in 1931. No doubt in Paris, as in the other capitals where radium has been available in this form, the treatment has been something in the nature of a clinical experiment of which the results are not yet known and in regard to which, as our own Commission has said, at least five years of further experience and coordinated research will be required before any final verdict can be expected. The disassembling of the bomb is in no sense a final and irrevocable act. It is simply proposed to redistribute its contents into four units each of one gramme. None of the tubes in which the radium is contained is to be broken up, and, even were this the case, its redistribution into smaller or larger units, though a highly technical matter, is one which would present no particular difficulty. The act does not mean (to use the words of an official communication to the press) that the Commission has lost faith or interest in bomb therapy, but that further experience is desirable before the treatment of patients with the larger type of bomb is continued under its auspices.

Mr. STANFORD CADE and his five co-signatories to the letter in the *Times* urged the immediate appointment by Parliament of a committee of inquiry to consider how best to advance radiotherapy, especially in its research aspects. They state, as we have noted, that certain types of cancer are better treated by the bomb than by any other method. There is evidently on this point a definite cleavage of opinion within the medical profession in this country and one that is hardly

Digitalin Granules "A. & H."

gr. $\frac{1}{240}$ ($\frac{1}{4}$ mg.)
Digitaline Cristallisée
(French Codex)
40 granules each containing gr. $\frac{1}{240}$ ($\frac{1}{4}$ mg.)
POISON
Manufactured in England by Allen & Hanburys Ltd. London, E.2
Digitaline Cristallisée
(French Codex)
40 granules each containing gr. $\frac{1}{600}$ ($\frac{1}{10}$ mg.)
POISON
Manufactured in England by Allen & Hanburys Ltd. London, E.2
gr. $\frac{1}{600}$ ($\frac{1}{10}$ mg.)

Digitalin Granules. "A. & H.," a British preparation, consist of the *Digitaline cristallisée* of the French Pharmacopœia. This substance is the most active principle of digitalis leaves. and, because of its reputation for uniform activity, it has long been popular, particularly on the Continent. Its use is recommended by high authority in cases where galenical preparations of digitalis have failed.

For Prescribing:
In tubes, containing 40 granules, 2/6 each
For Dispensing:
In bottles, containing 250 granules, 12/6 each
Subject to the usual professional discount.

Descriptive literature and clinical trial sample will be sent post free on application.

Allen & Hanburys Ltd., London, E.2

Telephone: 3201 Bishopsgate (10 lines) *Telegrams:* "Greenburys Beth London"

After Influenza

The Effective Tonic is "BYNIN" AMARA

The general action of "Bynin" Amara is manifested by increased tone of the nervous, muscular and cardiovascular systems. It stimulates the digestive organs, improves the flagging appetite, corrects anæmia and aids nutrition generally. The marked asthenia and nervous depression which are prominent features of the post-influenzal state, yield rapidly to its influence. A course whenever there is any *indication of lowered resistance is a valuable* safeguard against infection.

In bottles at 2/-, 3/6, 6/6 and 12/-

Descriptive literature and clinical trial sample on application.

COMPOSITION:
Quinine Phosphate
1½ gr.
Iron Phosphate
2 gr.
NuxVomica Alkaloids
equal to Strychnine $\frac{1}{60}$ gr.
"Bynin" Liquid Malt
1 oz.

Allen & Hanburys Ltd., London, E.2

Telephone: 3201 Bishopsgate (10 lines). Telegrams: "Greenburys Beth London."

nd scientific equipment. the perfect nursing home. ith all the resources of a modern hospital. It is un by a board of directors for profit, but the ishes of the medical staff will, it is understood. paramount, in respect of the interests of their harges. The chairman is the Duke of ATHOLL nd the house governor is Sir ERNEST MORRIS. ell known as the director of the London Hospital or many years. Thirty-six consultants form what known as the "medical group." Each of them as a consulting-room and an office in the building: hese they rent from the directors in the ordinary ay, and they have first call on the beds. The Duke of ATHOLL, however, pointed out in his peech at the opening that the clinic is not a "tied house" but that any member of the medical rofession can secure a bed for a patient if he wishes. When the clinic is full there will be two resident medical officers, but any general practitioner whose patient enters the clinic can continue to attend, together with the consultant of his choice. s in an ordinary nursing home, except that the use of the operating theatres is limited to surgeons on the staff of recognised teaching hospitals. Every nurse on the staff is State-registered and the porters and attendants are all ex-Service men personally selected by the chairman; and the chef comes, we learn, from a well-known restaurant. The pathological and radiological departments are run by a separate company formed by the medical group. Beyond a moderate interest on the money subscribed, all profits will be devoted to improvement of equipment and the reduction of fees to patients of the clinic who cannot afford the ordinary rate. Only members of the group will have the privilege of obtaining reduced rates for those under their care who cannot afford the customary rates, which will always be charged to any outside practitioners who make use of the laboratories.

The building occupies a site of two and a half acres and has cost over £430,000. The rooms are distributed over ten floors and there is nearly a mile of rubber-paved corridors, all of which are lit by a system of glass-fronted alcoves; hung across every corridor there is a glass sign-board bearing the name of every member of the staff. so that when he is wanted his name can be illuminated in all parts of the building. Nearly all the patients' rooms front on to the courtyard. so that they are as far as possible from street noise. Where necessary, double windows are provided. and the problem of vibration has been overcome by padding the steel foundations with heavy felt. Every room has its own hot and cold water-supply, telephone, bathroom, and lavatory, and all the furniture is of walnut or African mahogany covered with cellulose. so that no polishing is needed. Each bed has a three-button switch beside it, so that the patient can press a red light to indicate that he wishes to be left quiet, a blue light when he wants to call a nurse. and a green light when he wants to call a maid. These lights shine outside in the corridor and also show a small tell-tale light in the room to assure the patient that his apparatus is working. There are no bells or buzzers. One floor is to be devoted to children and another to dietetic cases, while the seventh floor is for maternity and includes two special labour rooms and a roof garden for the babies. On the eighth floor are the seven operating theatres. including a dental theatre and an ear, nose. and throat theatre. Each is equipped with sterilising. lighting, and ventilating apparatus, not of any predominant British production.

The cheapest room is priced at eight guineas a week, and the "luxury suites," at thirty-five guineas, include a second room for a relative or maid and a nicely furnished sitting-room. "This," said Lord MOYNIHAN at the opening, "is a new venture, a venture fraught with the deepest significance to the profession and to the public . . . a clinic to satisfy the most fastidious demands." The London Clinic should offer unusual opportunities for team-work among specialists, and for the collection of statistics.

◆

A SCHOOL HEALTH SERVICE.

IT was the tragedy of Dr. Parlane Kinloch's career that he just did not live to see the larger fruits of his administrative genius. His own department was strengthened and remodelled but the time was too short for the close appreciation of the difficulties of medical men and other health workers in the field, which was his special gift, to take full effect. In a letter to Sir Arthur Newsholme, written a day or two before his death, he admitted that his review of the health services with reference to efficiency and results was compelling him to the conclusion of the need for definite reorientation. "At this stage," he wrote, "I would illustrate my point by reference to any one of our services, say, the school health service. At the initiation of the service. I think we all generally took the view that, with a system of periodic examination of school-children, we should be able to detect divergencies from health and minor and major defects, the correction of which would prevent the development of more serious disease. The defects thrown up by the school health service are, in order of frequency, carious teeth, diseased tonsils and adenoids, enlarged glands, rickets, discharging ears, &c., and it is obvious that these conditions are either the late, and in some cases, the irreparable effects of malnutrition or the end-products of earlier infectious diseases, including catarrhal and respiratory infections. In other words, routine inspection is revealing conditions that cannot properly be remedied as detected, and it would appear that we must go much further back and secure the adequate nutrition of the expectant mother and of the infant and growing child in its earliest years; we must improve the diet to increase resistance to the infections whose end-products are revealed by school health inspection; and we must provide a medical service that will deal with infections in their earliest stages and so by early and intensive treatment prevent complications and sequelæ. The school medical service," Dr. Kinloch went on to say, "yields no evidence of the incidence of morbidity in child life. Whenever a child becomes ill, it disappears from the school health service and comes under the care of the family doctor." And he concluded with the pregnant remark: "It seems to me that we shall have to swing the whole service into the hands of the general practitioner and concentrate on fitting him to discharge the functions that this proposal requires of him."

likely to be reconciled by intervention from without. Lord DAWSON and Lord MOYNIHAN are unquestionably right in saying that the duty of instituting such an inquiry belongs to the medical profession itself. Doubts which have been raised as to the disposal of funds by the Radium Commission, and the competence of the Commission itself, could be set at rest by a public inquiry, if they had not already been set at rest by simpler means. But the ascertaining of clinical and experimental facts, the pooling of experience, and the weighing of conflicting views are the only bases of reconciliation and future action. These are the task of medicine.

◆

RHEUMATIC INFECTION IN CHILDHOOD.

IN Cardiff C. J. MCSWEENEY[1] finds that the incidence of rheumatic carditis is 5·8 per 1000 of the elementary school population, while W. G. SAVAGE[2] has estimated the incidence in Bristol at 7·7. The average figure for the counties round Bristol was in the neighbourhood of 2 per 1000, and this strongly suggests that there is some factor in urban life which plays an important part in rheumatic infection. MCSWEENEY notes that over 66 per cent. of the cases occur in the cold wet months of winter and spring, and that in over 73 per cent. the disease comes on between the ages of 5 and 10. There was no appreciable association of rheumatism with damp houses, dental caries, state of the tonsils, or frequency of sore-throats. Cardiff is fortunate in having special hospital accommodation for these children, and it appears that at least one bed for every 1000 of the school population is needed for their efficient treatment. The value of this hospital treatment is shown by the fact that, in the period reviewed, of the total 222 children admitted only 29 had normal hearts, but 135 were discharged with no demonstrable cardiac lesion. Incidentally it was observed that children treated in open-air shelters improved more rapidly and relapsed less often after discharge than those who slept indoors. The Cardiff experience also supported the opinion that tonsillectomy does little to prevent the onset or decrease the relapses of rheumatism in childhood.

Six hundred of the Cardiff children were grouped according to their social status in an attempt to assess the significance of gross environmental factors in the ætiology of the disease. It was shown once more that rheumatic children are seldom met with in well-to-do homes, and also that the incidence is greatest not among destitute recipients of public assistance but among those who, without actually suffering privation, have a struggle to make ends meet. That rheumatic infection may occur amongst public school-children is shown by W. H. BRADLEY, who has lately recorded[3] two epidemics in a public school. These epidemics were closely associated, and ran parallel with epidemics of sore-throat due to a hæmolytic streptococcus. The rheumatism followed the nasopharyngitis, when this was recognisable, after an interval, in the way described by B. E. SCHLESINGER and W. SHELDON, which is held to suggest an allergic state. In the two epidemics different strains of streptococcus were isolated, and the sore-throats which they produced were distinct in their clinical appearances. BRADLEY therefore agrees with SHELDON that while rheumatism itself is not infective the preceding nasopharyngitis, which *sensitises the patient*, probably spreads as a droplet infection.

A difficulty that confronts all students of rheumatic carditis is how to know when the patient may safely be released from active restraint and allowed to return, partially at any rate, to a normal life. This is largely dependent on the question, not yet definitely answered, whether the morbid process is a drawn-out smouldering infection like tuberculosis, or consists of a series of relapses with cessation of activity in the interval. White blood-cell counts have in general proved of little value in determining the activity or otherwise of the disease, but in our issue of Jan. 9th W. W. PAYNE and also F. BACH and N. GRAY HILL showed that the sedimentation rate of the blood may be useful in this respect. A raised pulse-rate has long been regarded as an indication of a progressive cardiac lesion, but since the pulse-rate is easily affected by purely psychic factors its value as an index of activity is largely vitiated. SCHLESINGER[4] has tried to get over this difficulty by studying the pulse-rate during sleep. He finds that the normal sleeping pulse-rate is on the average 10 lower than the "alert" rate. From his study he believes that if the sleeping pulse-rate is raised and approximates to the alert rate so that the normal difference is abolished, we have an indication of active carditis. Even if this difference is absent, a sleeping pulse-rate persistently above normal is in his opinion strongly suggestive of activity.

◆

THE LONDON CLINIC AND NURSING HOME.

IT has often been pointed out that the most modern and elaborate equipment for the treatment of disease is available in this country only for the poor and the rich. But though the rich can obtain the advantages, the different branches of treatment are never found under one roof. While an expensive nursing home may offer a comfortable room, a good cuisine, first-class nursing, and an up-to-date theatre, the pathological investigations will have to be made somewhere else and usually the X ray examination somewhere else again, while consultants who have equipped themselves with special diagnostic apparatus may have to be visited in yet other neighbourhoods. Even the very rich find the procedure dear. It is the object of the promoters of the London Clinic and Nursing Home, which was opened by the Duchess of YORK last week, to provide full facility for the diagnosis and treatment of disease under one roof and *at a price which the middle class can afford.*

The great building at the north end of Harley-street and Devonshire-place claims to be, in design cases. Miss Mary Botsford, of San Francisco, the President of the Associated Anæsthetists of the United States and Canada, pleads for the recognition of "anæsthesiology" as a medical specialty by the American Medical Association and a requirement for its teaching in the medical schools. The last appears to us of vital importance. Without well-qualified teachers and compulsory attendance of students, anæsthesia can never receive the attention which it deserves from the point of view of the safety and the welfare of the patient. In this country we have gone some way in this proper direction, but the future is likely to see us go still further and we make no doubt that the United States will emulate our action, if they do not set us an example by making greater strides than ourselves.

A SYMPOSIUM ON PROSTATECTOMY.

THE ideal of primary closure of the bladder after suprapubic prostatectomy has for some time been before the profession. It is obvious that if the bladder can be closed by primary suture convalescence will be shortened, and many of the patient's discomforts prevented. But many of those who have attempted to gain this advantage for their patients have finally abandoned closure either because they considered it dangerous or because they found the technical difficulties of the operation insuperable. At a discussion on prostatectomy reported in the *Journal of the American Medical Association* (1931, xcvii., 1768), Dr. A. H. Peacock, of Seattle, tried to show that suture and closure is not a difficult operation, that no special instruments are required for carrying it out, and that the ideal behind it is surgically correct. In order that closure may be effected, two conditions are essential, first, complete hæmostasis, and, second, unobstructed urethral drainage. In achieving the former reliance is placed on properly placed sutures. A good view of the base of the bladder is obtained by means of a self-retaining retractor, and the sutures inserted either by means of a Young's boomerang needle, or else by using an ordinary long holder with a short curved needle. The second essential of drainage is obtained by an in-dwelling catheter, preferable a No. 26 or 28 French whistle-tipped catheter. This is anchored in position by passing one of the prostatic sutures through its eye. The catheter is removed at the end of three or four days and a smaller one inserted in its place. The average time for the in-dwelling catheter in a series of 50 cases was ten days. The incidence of wound leakage was small, and when leakage did occur it usually indicated an obstructed catheter. The average time before normal voiding was 12 days. It was claimed that by closing the bladder the comfort of the patient was greatly increased and a great saving in dressings effected. Post-operative bleeding was practically eliminated, and sloughing of the suprapubic wound never occurred.

Although there are few surgeons who would deny Dr. Peacock's contention that closure of the bladder is in keeping with general surgical principles, there would appear to be still fewer who at the present moment are prepared to follow his lead. Amongst those who took part in the discussion that followed his paper, as well as in a similar discussion held in this country about a year ago,[1] it was the general opinion that closure of the bladder is too dangerous to be adopted as a routine measure. However carefully sutures are placed, and however great the attention paid to drainage, there must always be the risk of clot retention and of obstruction. But even if Dr. Peacock, and Mr. S. H. Harris, of Sydney, have not succeeded in persuading genito-urinary surgeons in general to follow their lead they will have the satisfaction of knowing that they are working in the right direction, and that at some not too distant date their names will be recorded as pioneers in prostatic surgery.

In a contribution to the discussion by Dr. Edwin Davis, of Omaha, great emphasis was laid on the value of sacral anæsthesia in perineal prostatectomy. Anæsthesia is undoubtedly an important consideration in prostatectomy, and both inhalation and intraspinal anæsthesias carry with them definite risks. The objection that has been urged against sacral anæsthesia is that it is difficult to carry out, and that it is unreliable. Dr. W. W. Babcock has even stated that it is only efficient in 45 per cent. of cases. It is possible, however, that the reputation of sacral anæsthesia has suffered by confusion with the far less efficient method of caudal anæsthesia. At any rate, Dr. J. S. Lundy has reported that in a series of 318 cases of suprapubic prostatectomy carried out under sacral block combined with infiltration of the anterior abdominal wall, good anæsthesia was obtained in 96·5 per cent. of cases. Dr. Davis's analysis of 378 consecutive cases of perineal prostatectomy performed under sacral anæsthesia reveals the importance of technique. He found that although in the first series he had 20 per cent. of failures, amongst the last 229 cases there has not been one failure. We may therefore assume that provided the method is skilfully carried out it is extremely reliable. The objection that it demands considerable time and trouble on the part of the surgeon is less easily put on one side. The time required depends on the skill and experience of the operator. In Dr. Davis's hands sacral anæsthesia can be achieved in 12½ minutes. The maximum time required, in cases of unusual difficulty, was 30 minutes. Dr. Davis believes firmly that the use of sacral anæsthesia has contributed greatly to the lowering of his mortality-rate. In his series of 378 cases of perineal prostatectomy he has only had nine deaths, giving a mortality-rate as low as 2·38 per cent. Whatever the difficulties entailed in learning the technique of sacral anæsthesia, it would seem fully worth while to overcome them.

The last paper of the symposium deals with another aspect of the subject—namely, whether it is possible in certain cases to relieve obstruction by methods less drastic than prostatectomy. It is curious that this question should have provoked so many heated discussions amongst genito-urinary surgeons. There are two camps—those who are enthusiastic on per-urethral methods, and those who condemn them as worthless, and, because they give a false sense of security, even dangerous. The truth surely lies midway between these two schools of thought. Enthusiasts have erred in attempting to apply the method to cases for which it is unsuited, and opponents have too sweepingly denied its utility in those for which it is appropriate. To the latter we would commend Dr. Davis's paper. No one who is not blindly prejudiced could read it without being impressed with the results given by resection in his hands. The operation has the great advantage of being a comparatively trifling one, and of incapacitating the patient for only a short time. The average

ANNOTATIONS

BRITISH POST-GRADUATE MEDICAL SCHOOL.

ALTHOUGH the post-graduate school at Hammersmith is unlikely to come into being before October of next year at the earliest, the discussions for its establishment have at last reached the stage when plans have been approved both by the London County Council and the governing body of the School. These plans include developments and adaptations of the Hammersmith Hospital, of which Sir Thomas Carey Evans is now director. Provisional plans were originally prepared for a comprehensive scheme estimated to cost £250,000, but in view of the national financial position which developed last September it became apparent that the Government were not prepared to expend so large a sum. The L.C.C. architect was consequently directed to prepare a less ambitious scheme, the total cost of which was estimated not to exceed £200,000, it being understood that the Government's contribution towards the cost would be about £100,000. It is the plans for this modified scheme which have now been approved. The new scheme provides not only for a medical school, but for casualty, receiving, and out-patient departments in two new blocks, a new ward, a central dressings sterilising room, massage and light sections. The new blocks will displace certain existing portions of the hospital buildings and, apart from the cost of equipment and furniture, are estimated to cost £160,000. Working drawings will now be taken in hand. In the meantime it will be noted with interest that the plastic surgery unit formerly at St. James's Hospital has been transferred to Hammersmith, where Sir Harold Gillies will act in an honorary capacity as chief surgeon. Mr. T. Pomfret Kilner is acting in a temporary capacity as plastic surgeon, and an assistant plastic surgeon is to be appointed.

THE DRINK PROBLEM.

BEFORE the appointment of the Royal Commission, the report of which was recently discussed in THE LANCET, a group of distinguished public men and women started an inquiry into the medical, social, and economic aspects of the alcohol problem in Great Britain. The only instruction they gave their experts and investigators was that the facts must be presented without bias or prejudice. The results have now been published in two volumes.[1] The first, which may roughly be called the medical volume, covers much the same ground as the admirable symposium published by the Medical Research Council for the Liquor Control Board in 1924. The account now published is sane and reasonable, though enthusiasts will find its impartiality rather dull. The authors have the advantage of being able to draw on Dr. H. M. Vernon's excellent book published in 1928. The chapter on the mental effects (apart from insanity) is easily the best; fortunately, it has also become, nowadays, the most important. As the editors remark in the preface, some differences of opinion among the cited authorities are inevitable; there seems too to be some mental conflict among the experts who write the various chapters. Thus, on p. 84 it is opined that "medicinal doses" of alcohol are too small to make any appreciable difference in acute infections; on pp. 90 and 91 statistical evidence is quoted at some length to show that alcohol does either no good or harm in the treatment of pneumonia; on p. 220 the same experts say "the treatment of fevers would be difficult indeed were this drug [alcohol] to be entirely removed." It is perhaps well that the reader is warned not to expect *ex cathedra* pronouncements. Each chapter has a useful list of references to the literature.

Most medical men will find the second volume less familiar and more interesting. It deals with the economic aspects of the production and consumption of alcoholic drinks, and with the relation of drink to industrial efficiency, poverty, and crime. Fresh, careful, and apparently impartial inquiries reveal that in industry there has been a great diminution in drinking and that the younger generation are very different from their fathers; they must needs keep better time in the works and outside they want to dance and play games and have decent homes, and so give drink the go-bye. Investigations in York and Edinburgh showed that about 25 or 30 per cent. of the whole of the poverty in a typical working-class district was caused wholly or partly by drink. Of various groups of crime, from 10 to 40 per cent. were found to be alcoholic in origin. Whether the employment efficiency of the drink trade is as high as that of other industries is left an open question; it seems to involve about 400,000 persons and their activities led to our spending on the average 124s. per head of the population of Great Britain in 1930. The sum of the whole matter seems to be that the harmful effects of alcoholic excess are indisputable and not disputed. What is needed now is a correct evaluation of the influence of small and moderate doses on judgment, dexterity, and other finer activities of the nervous system.

TRAINING IN ANÆSTHETICS.

THE lively interest in anæsthetics and the rapidly growing importance attached to this branch of work in America are well illustrated in the January-February number of *Anæsthesia and Analgesia*. It is obvious that the days of the "technician" or trained lay anæsthetist, whether a nurse or otherwise, are numbered in the United States. California has already abolished this kind of administrator, the State Legislature when amending the Medical Practice Act having adopted a resolution of the California State Medical Society to the effect that "the administration of an anæsthetic is always the function of a legally qualified medical practitioner," and that "the society condemns under all circumstances the training and qualification of lay persons as anæsthetists." The American College of Surgeons in their "Hospital Standardisation Report" lay it down that "the rapid advance made in anæsthesia during recent years has greatly improved methods of administration . . . the administration of anæsthetics in hospitals has considerable room for improvement. This can be accomplished in great degree by employing only qualified experienced persons in this department." To assure safety and efficiency there should be (1) an organised department of anæsthesia in charge of a qualified medical graduate who has had special instruction in anæsthesia; (2) a staff of trained and experienced assistants. The report also points out the desirability of complete examination and review of laboratory findings for every patient before operation and of the efficient following up of all anæsthetic unhappiness, the kind of home where the child never knew what was going to happen next. Yet there seemed to be a certain inherent factor as well, since children in exactly comparable surroundings might fail to show anxiety symptoms. Dr. Moodie thinks that he has now collected some cases where it is absolutely certain that the child cannot, in the ordinary sense of the word, have known of certain home situations such as conditions leading up to a divorce, and yet it has quite clearly "sensed" the position and taken refuge in some form of flight. He deprecated the value of the intelligence quotient alone, but emphasised by illustration the tremendous amount of information that can be obtained by an intelligent psychologist who makes notes of the child's temperament while putting him through the ordinary intelligence tests. In this way, he said, much could be learnt about the child's emotional reactions without any of that difficult, tedious, and almost invariably destructive prying into his mind which is essential if a temperament estimate is to be made directly. The child takes the intelligence tests as a kind of school examination and is unaware of the observation that is being made at the same time. He was able to give two answers to the question: why does a child adopt any particular form of bad behaviour? In the first place the particular form adopted is nearly always a regression: if the parent complains that the boy wets the bed, the history will usually show enuresis at an earlier age. In the same way, if a child assumes an attitude such as shyness or aggressiveness, a review of the past will usually show that this attitude has been successful in earlier days. In the second place there is the factor of direct example; the need for bad behaviour having arisen in the child's psychology, he may simply copy something that he sees around him or that is suggested to him.

It is of interest to learn that Dr. Moodie could find in his clinic experience no evidence that these behaviour patterns are inborn.

INJURIES OF THE COMMON AND HEPATIC DUCTS.

THERE can be few operations in surgery which call for greater craftsmanship and resource on the part of the surgeon than those undertaken for the repair of injury to the bile-duct. Howard M. Clute,[1] discussing 25 cases of this condition operated on in the Lahey Clinic at Boston, divides the causes of stricture of the common duct into four groups: (1) those resulting from cholangitis; (2) those due to ulceration round a stone; (3) those resulting from severe blows or crushing injuries; and (4) those caused by injury to the ducts inflicted at the time of some operation on the biliary apparatus. Of the cases under review, 20 belong to group 4, one to group 3, and four to group 2. Clute thinks that cholangitis is a very rare cause of stricture, basing his view on the fact that it has not occurred in his practice. E. S. Judd,[2] of the Mayo Clinic, on the other hand, considers cholangitis of the obliterative type to be the cause of a considerable proportion of strictures of the common duct that have been classified as traumatic, and gives evidence in support of his views. Clute discusses the common causes of accidental injuries of the common duct during cholecystectomy, and rightly urges that where adequate exposure of the common and cystic ducts cannot be obtained—either because of technical difficulties or because of lack of operative skill—the procedure of choice is cholecystostomy. Should the duct be injured during operation, and if the injury is recognised at the time, its repair at once is not only relatively easy, but is usually followed by good results. Unfortunately the surgeon who is most likely to injure the duct is least likely to recognise what he has done, and the increasing frequency of this type of case makes it essential to realise the fact that gall-bladder surgery is not for the inexpert surgeon, for whom it holds many pitfalls.

The cases reported by Clute were treated by a variety of methods depending on the state of the injured duct. He has had no experience of either Walton's or Mayo's methods of anastomosis by means of a duodenal flap—methods which have given very good results in a number of cases. He has, however, performed 12 operations upon nine people with the object of establishing a complete external biliary fistula, and has succeeded in three. Several of these attempts were on very ill patients who had had multiple previous operations. Complete external biliary fistulæ have been transplanted into the stomach or duodenum seven times, either in cases where the fistula existed already, or after it had been produced surgically. Of these seven cases, three have been satisfactory, and four complete failures. Waltman Walters,[3] of the Mayo Clinic, reports five cases of the transplantation of complete external biliary fistulæ, with one death. Two cases had satisfactory results, and two were much improved but had some persisting symptoms. There can be no doubt that this method of establishing a complete external biliary fistula, and then transplanting the fistula into the stomach or duodenum, is one to be reserved only for cases in which the proximal end of the injured duct cannot be found, or when found is unsuitable for direct anastomosis. It is a formidable procedure, with many failures, but in successful cases it gives a possibility of relief to patients for whom otherwise little could be done.

PSEUDOPREGNANCY.

PSEUDOPREGNANCY is a well-known phenomenon in lower animals and is seen most simply in such animals as the rabbit and ferret which ovulate after coitus. If the buck is vasectomised in these animals, coitus, though sterile, is followed by ovulation and corpus luteum formation. The animals then develop hypertrophy of the breasts, proliferative changes can be demonstrated in the uterus, and in the case of the rabbit pseudopregnancy terminates about 19 days after the sterile coitus by the animal preparing a nest and by the secretion of milk in the breasts. In the majority of domesticated animals ovulation is spontaneous and takes place during the œstral phase of the sexual cycle. It has been shown that similar proliferation of the endometrium can be demonstrated during the corpus luteum phase in the absence of pregnancy, in the case of the bitch (Marshall and Halnan [4]), the sow (Corner [5]), the marsupial cat (Hill and O'Donoghue [6]), and the opossum (Hartman [7]). For these reasons Heape's scheme for the sexual cycle of animals has been modified and is now regarded as consisting of stay in hospital in this series was four days. Dr. Davis has designed an instrument of his own for the carrying out of resection. His resectoscope consists of a sheath with a finestrum ⅞ of an inch in length near the beak, an obturator to aid introduction, an indirect vision examining telescope, and the working parts. The working parts consist of a light carrier, water conduit, direct vision telescope, and a loop electrode. The loop is placed in front of the direct vision telescope, and is made to engage the obstructing tissue to be removed. By means of this instrument as much as 24·7 g. of prostatic tissue has been removed at a single sitting from an enlarged prostate. In only seven out of a total of 246 cases was it necessary to repeat the operation. Surely this is a record which would justify any surgeon in employing this method in suitable cases. In the discussions that followed, to which many prominent American urologists contributed, many opinions were expressed. General agreement was reached on one important point—that it was impossible to regard any particular set operation as applicable to all cases. The expert genito-urinary surgeon must be prepared to do either the suprapubic or the perineal operation, and to select the technique that is suited to the particular case with which he has to deal. Either of these operations may be desirable, or the comparatively trifling procedure of resection may be indicated. The expert must be master of all three methods of treatment, and should not be wedded to any one of them.

HOSPITAL COÖRDINATION IN MANCHESTER.

At the recent annual general meeting of the trustees of Manchester Royal Infirmary, Mr. Wilson Hey, chairman of the medical board, made some pointed comments upon what he described as the want of coördination among the local hospitals and the overlapping of services which "results in wastage of money and effort, and consequently in unnecessary suffering to the patients." Mr. Hey pointed out that the infirmary, with its satellites at Cheadle and Monsall, possesses specialists in every branch of medicine and is "almost an international hospital," but it cannot cope with the demand. "Patients wait for months in suffering for admission to its wards, while beds lie empty for months elsewhere." According to the latest report of the Manchester voluntary hospitals there is a daily average of 260 empty beds in the city out of a total of a little over 2000, excluding the municipal hospitals. The figures allow for keeping emergency beds in readiness. Mr. Hey went on to say that "on account of the want of organisation, urgencies and accidents and also chronic patients have to be taken first to one hospital and then transferred to another, often enough on the same day. Our expert abdominal surgeon is compelled to deal with fractures and our neurologist to operate upon abdomens. The inexperienced has thrust upon him cases requiring wise and rare judgment, and the experienced often wastes his time on trivialities." So far from the poor-law hospitals having fallen into a common line with the voluntary hospitals as the medical profession had expected, they remain isolated units still, as for the last 20 years, the dumping ground of the trivial, chronic, and dilatory cases, with which the rush of the general hospital cannot cope. "Our magnificent municipal hospitals," he said, "are worthy of better things than this."

In 1931 the Royal Infirmary dealt with 11,847 in-patients and 48,693 out-patients; there were, in addition, 1220 in-patients in the Barnes Convalescent Hospital at Cheadle. The cost per annum per bed occupied at the infirmary was £177 14*s.* 11*d.*, an increase over the previous year of nearly £10, and the average cost of each patient £8 5*s.* 7*d.* At the Barnes Hospital the cost per bed per annum was £89 14*s.* 10*d.* The total ordinary income of the infirmary and the Barnes Hospital was £94,629, against £96,653 in 1930 and £101,946 in 1929.

WHY DO CHILDREN BEHAVE BADLY?

The Child Guidance Clinic in Islington has now been running for three years and will in a very few days' time see its thousandth patient. Dr. William Moodie took the opportunity when addressing the Medical Officers of Schools' Association last week to give a résumé of the results and conclusions arrived at as the result of his work there. He laid it down in the first place that bad behaviour was not gratuitous and that its cause could often be found, the criterion for "cause" being that its alteration altered the behaviour. He declared himself as being unable to accept as satisfactory either the theory of original sin or the explanations of psycho-analysis; the only practical way, he said, was to consider the child as a person who must conform, as far as in him lay, to society and the standards of decent behaviour. There must be a compromise between freedom and repression, between individual tendencies and the needs of society. There had in recent years been a universal tendency to lessen repressive measures, a tendency which had perhaps gone too far. The child must be considered as a member of society and not merely as a unit. The children sent to his clinic were almost invariably referred on account of some social difficulty. Half of them came from elementary schools and a quarter from public schools, the remainder being of pre- or post-school age. In this connexion Dr. Letitia Fairfield, in the subsequent discussion, recalled an interesting inquiry into the offences considered most grave by a series of school teachers. At the top of the list had come all the symptoms of rebellion against authority, headed, in the case of women teachers, by swearing. At the bottom of the list, considered by the teachers unimportant, were those flights from reality—such as shyness, day-dreaming, and lack of attention—which psychologists know to constitute a far more serious threat to the value of the future citizen. Dr. Fairfield pleaded that teachers should learn to appreciate better the significance of bad behaviour in their children.

Although backwardness was the complaint for which the children in Dr. Moodie's clinic were referred in 25 per cent. of cases, and although it actually proved to be a factor in 50 per cent. of cases, the intelligence curve corresponded very closely to that of the population as a whole. After backwardness the commonest causes of complaint were, in order: stealing, nervousness, unmanageableness, lying, temper, enuresis, stammering, truancy, and lack of concentration. It had been found that these difficulties were nearly always grouped in fives; a child very seldom had only one such symptom. When the children were examined, gross physical defects were not commonly found—naturally such cases would go to a general hospital—but it was extremely common to find evidence of fatigue and conditions which in an adult would certainly be described as hyperthyroid anxiety states. Often these arose from environmental factors—fatigue from loss of sleep due to noisy or overcrowded bedrooms, and anxiety from broken homes, illegitimacy, and marital

SPECIAL ARTICLES

POLIOMYELO-ENCEPHALITIS
IN VICTORIA (1925–1931).
TREATMENT BY HUMAN IMMUNE SERUM.

BY JEAN MACNAMARA, M.D. MELB.,
N. MEDICAL OFFICER TO THE PHYSIOTHERAPY DEPARTMENT,
CHILDREN'S HOSPITAL, MELBOURNE; CONSULTANT TO
THE VICTORIAN COMMITTEE FOR POLIOMYELITIS,
APRIL, 1925, TO AUGUST, 1931;

AND

F. G. MORGAN, M.B. MELB.,
ECTOR, LABORATORIES DIVISION, COMMONWEALTH DEPARTMENT
OF HEALTH, AUSTRALIA.

IN April, 1925, an increase in the incidence of liomyelitis in Melbourne suggested the possibility a severe epidemic, and an organisation[1] was formed prepare for this emergency. The six objectives en determined have been followed during the riod under review.

1. The preparation of a supply of serum from the od of persons who had had an attack of polio-yelitis within recent years.
2. The education of the medical profession in the ndrome of the preparalytic stage, and the education profession and public to the importance of diagnosis fore paralysis.
3. The provision to practitioners of help in diagnosis a consultant prepared, if the clinical findings stified the procedure, to carry out lumbar puncture d examination of the cerebro-spinal fluid at the dside.
4. Control of the distribution of serum to obviate aste and the possibility of bringing the therapy to disrepute by the use of serum in unsuitable or nproven cases.
5. The collection of clinical records to permit sessment of the value of the therapy.
6. The attempt to ensure that every paralysed atient received adequate after-care by splinting and uscle re-education.

Preparation of Serum.

By various means suitable donors were traced hrough searches made at hospitals, splint-makers, urgical boot-makers, records of notifications and avalid pensioners, house-to-house visits, and the liagnosis verified by examination of the residual aralysis. Fortunately, 12 young adults survived he epidemic which occurred during April and May, 925, and these proved our most valuable donors or some years—giving blood gratuitously until 1928, hen a system of payment was introduced. Details f the preparation of serum have been published n the *Medical Journal of Australia* in 1927[2] and 1928,[3] but in 1930 slight modifications of the method resulted in a higher yield of serum, thus lowering the cost of production. A brief description of the method will be given, because it is possible that the method of preparation adopted may influence the results obtained in treatment.

The donor being recumbent, the band of a sphygmomanometer is wrapped round the arm and the skin over the elbow cleansed with ether, soap, and acetone-cyllin-methylated spirits lotion. Sterile towels are applied. The needles used are freshly sharpened rustless steel needles of large calibre (1·65 mm. gauge). After boiling, the needle is rinsed with oxalate solution and connected by means of sterile paraffined rubber tubing to glass tubing, and thence to the receiving vessel, which contains a measured amount of 10 per cent. potassium oxalate solution. The arm band is inflated until the vein is evident, the needle being inserted with the point directed towards the hand. In most donors blood flows most quickly when the sphygmomanometer registers 30 mm. Hg. but the optimum pressure varies during each bleeding. The donor is told to open and shut the hand slowly, firmly, and steadily, and the receiving vessel is gently shaken as the blood enters. Ample supplies of blood have been obtained by venepuncture. Neither venesection nor aspiration has been found necessary. The quantity of blood withdrawn has been regulated by the donor's wishes, occupation, and condition, not by any limitation of the technique described. Table I. shows the amount of blood withdrawn during the period under review.

TABLE I.

Year ..	1925–1927.	1927–1928.	1929.	1930.	1931.	*Total* 1925–1931.
Total volume of blood during period	4,650 c.cm.	20,563 c.cm.	15,370 c.cm.	18,870 c.cm.	24,585 c.cm.	84,038 c.cm.
Number of bleedings	34	53	28	35	49	199
Average amount of blood withdrawn per bleeding	136·7 c.cm.	388 c.cm.	545 c.cm.	539 c.cm.	501·7 c.cm.	422 c.cm.

A sample of blood is taken for the Wassermann test from each specimen withdrawn. The collecting vessels containing fluid blood are taken to the laboratories where the blood is centrifuged. The supernatant plasma is then syphoned from the underlying closely packed corpuscles. The plasma from each patient is kept separate until the report of the Wassermann test is received, when the various quantities are pooled. In bleeding 83 persons we have not had a positive Wassermann reaction. After pooling, the plasma is distributed into clotting jars to which is added calcium chloride solution of specific gravity 1022, in amount as calculated from the table printed in the earlier publication.[2] A clot quickly forms, is expressed from the serum by means of superimposed brass weights, and the serum is then altered through Seitz E K special type of filter disc. No antiseptic has been added, but great care is taken during the procedure. A second filtration through a bacteria-proof filter is made, and exhaustive tests for aerobic and anaerobic organisms at 37° C. and at room temperature are made upon the samples of the serum in bulk. The serum is distributed in sealed ampoules, each containing 10 c.cm. of serum, and further sterility tests are made at the time of bottling. During the 21 days after withdrawal of blood the donors are watched for the development of any disease, such as measles, caused by filter-passing organisms. Table II. shows the percentage yield of serum and the average yield per donor.

TABLE II.

Year ..	1925–1927.	1927–1928.	1929.	1930.	1931.
Number of bleedings ..	34	53	28	35	49
Volume of blood obtained	4,650 c.cm.	20,563 c.cm.	15,370 c.cm.	18,870 c.cm.	24,585 c.cm.
Volume of serum obtained	1,789 c.cm.	7,820 c.cm.	6,050 c.cm.	8,500 c.cm.	12,500 c.cm.
Percentage yield of serum	38·2	38	38·9	45	50·8
Average yield of serum per donor	52·6 c.cm.	147·5 c.cm.	216 c.cm.	242·8 c.cm.	255·1 c.cm.

In 1930 the centrifuge was first used, and an increase in the percentage yield will be noticed for that year. The highest yield of serum from a single pool was 55·5 per cent., composed of serum from nine donors. In the earlier years the serum was grouped according to the interval which had elapsed since the onset of the disease of the donor, but in 1930 this method was abandoned, and we have in each group pooled sera from eight to eleven donors affected in pro-œstrus and the corpus luteum phase or the phase of pseudopregnancy. In the normal human menstrual cycle ovulation occurs about the fourteenth day after the beginning of the last menstrual period and an active corpus luteum persists in the ovaries until shortly before the onset of the menstrual discharge. The premenstrual phase of the human menstrual cycle is therefore homologous with the experimental pseudopregnancy of the rabbit and ferret and with the pseudopregnancy phase of the sexual cycles of such animals as the bitch and sow. In a recent paper D. Macomber [8] attempts to identify a separate clinical state of pseudopregnancy in the human female. Two cases are described in which patients passed decidual tissue from the uterus after having been 11 and 14 days overdue with their periods. In both cases chorionic villi could not be found in the discharge. In one case the husband was proved to have aspermia, in the other the husband's fertility was shown to be extremely low. The interpretation placed upon these cases is that they represent comparable states to the pseudopregnancy of lower animals. This interpretation of the two cases demands severe criticism. In one of the cases the patient is stated to have had irregular menstrual periods, in the other no details are given of the past menstrual history. It is not uncommon for women to have prolonged menstrual cycles and Wilfred Shaw [9] has shown that such cases can be attributed to irregular ovulation; it is therefore possible that the two cases can be explained along these lines. During the late premenstrual phase of the cycle the stroma cells of the endometrium hypertrophy to such a degree that they resemble the decidual cells of early pregnancy; indeed it is often difficult to distinguish between the decidual reaction of the late premenstrual phase and that of early pregnancy. Similarly ectopic decidual cells can be demonstrated in the ovaries during the late premenstrual phase of the cycle. Macomber's explanation of his cases is therefore unconvincing, for both the missed periods and the discharge of decidual tissue from the uterus can be accounted for without resorting to the hypothesis of a pseudopregnancy. Moreover, as has been indicated above, the premenstrual phase of the normal cycle is homologous with the pseudopregnancy of lower animals.

THE PAGET TRADITION.

Sir James Paget had many contemporaries of distinction but none of them has so captured the imagination of a generation that never knew him. His "Memoirs and Letters" are read and re-read by many who ordinarily have little taste for matters historical. When Prof. Grey Turner received the Henry J. Bigelow medal of the Massachusetts Medical Society at Boston last June it seemed quite natural to him and to his hearers that his address[10] should be about the "Paget tradition." There were special reasons, too, for the choice of subject. Paget was a man after Bigelow's own heart; in 1882 he was elected an honorary member of the society; and in company with Dr. Harvey Cushing, another member of the society, the lecturer was one of the six perpetual students of Paget's old hospital. Most of my teachers, Prof. Turner remarked, had come under the spell of Paget, with them his example was a tradition, from them the torch was thrown, and I felt I was only fulfilling a sacred trust to hand it on. Foremost in the Paget tradition he put his example as a worker, for like John Hunter his friends always found him employed, and it has been said that he so loved work that he estimated the worth of his acquaintances by their output of it. In public duty he was punctilious to a fault and careful of the time of others, as he would expect them to be of his own. As a medical writer he had no rival, using pure and perfect English without effort. In an age of orators he was acknowledged one of the best speakers of his time. Many of his published lectures rank among the classics of medical literature and are read to-day for their grace and charm, as well as for their wisdom. He made great contributions to clinical surgery, and his original papers on the diseases of the breast and of the bones associated with his name still remain complete and perfect descriptions. He might, concluded Prof. Turner, have been a success in any honourable walk of life, but he had chosen the profession of medicine, he loved his avocation, and had the highest sense of the importance and dignity of his calling. And in simple and reverent language, enhanced by apt quotations from Paget's writings, Prof. Turner drew a picture of the man as he lives in our memories, with his tenderness and austerity, the light heart of his seriousness, the gentleness of his firmness.

VOTING AT EPSOM COLLEGE.

WE are asked to give publicity to the following statement: "Although the Governors of Epsom College unanimously decided at an extraordinary general meeting in June, 1931, to take the necessary steps to abolish the voting system, no change can be made until the scheme has received Parliamentary consent. The earliest date at which Parliament can sanction the proposed legislative changes, coupled with the statutory requirements and other unavoidable preliminaries of an annual election by votes of the governors, makes the cancellation of this year's voting in June impracticable, and therefore it will be necessary to adhere to the system of voting for the year 1932. Voting papers will be forwarded to all governors in due course."

BLOOD-GROUPS AND PATERNITY.

IN Dublin lately the blood-group test of relationship was accepted as evidence, for the first time, it is said, in any court in the British Isles. A district justice had made a maintenance order against an elderly man on the complaint of a young woman on behalf of her illegitimate child. The defendant appealed to the circuit court, and evidence was produced to show by blood-grouping that he could not be the father of the child. The test was carried out in the presence of the solicitors of the two parties by Dr. G. C. Dockeray, Dr. J. H. Stephens, and Dr. J. McGrath. Other evidence was also produced, and the judge reversed the decision of the district justice. The test is widely used in Germany, Austria, and Scandinavia,[1] but, as already stated, we do not know of its application in this country. It may be recalled that the precipitin or immunological test for human blood was accepted in criminal cases in Ireland for some years before it appeared in the courts of Great Britain. It was introduced to Ireland by the late Prof. E. J. McWeeney.

WE regret to announce the death on Wednesday, Feb. 24th, of Sir Frederick Andrewes, F.R.S., Emeritus professor of pathology in the University of London.

e spine into hyperextension. If asked to fold his ms he tries to do this, but quickly reverts to the ipod position.

Differential Diagnosis.

The differential diagnosis [11] covers a wide field of nical medicine, and cannot be dealt with in detail re. The suspicious cases seen in consultation ring the six-year period may be classified as llows :—

(a) The group in which clinical examination has rendered nbar puncture unnecessary. (1) Acute febrile diseases ich may be imitated by the preparalytic stage of polio-elitis: pneumonia, tonsillitis, influenza, otitis media, elitis, the exanthemata, dysentery, sunstroke, and laria. This group has caused the greatest difficulty. Cases in which poliomyelitis is suspected because of e inability to use a limb or because of the development of imp, the actual cause being: injury, acute rheumatism, uinal adenitis, scurvy, syphilitic para-epiphysitis, osteo-elitis, hysteria, peripheral neuritis, lead poisoning, htheritic paralysis, tetany, erythrœdema, spinal cord mours, or lesions of cerebral vessels.

(b) The group in which examination of the cerebro-spinal id is required: meningitis, tuberculous, cerebro-spinal, [illegible] streptococcal, staphylococcal, or influenzal; [illegible] complications of typhoid or parotitis, sub-arachnoid hæmorrhage, tetanus, uræmia, ningo-vascular syphilis, encephalitis following varicella vaccinia, encephalitis lethargica.

It has been strongly emphasised that even in mes of epidemic, in the absence of definite indication, mbar puncture for diagnostic purposes in cases of ute illness is not justifiable, but that every patient ffering from an illness for which a definite cause nnot be found by careful clinical examination ould be carefully watched and frequently -examined in order to detect the first evidence of eningeal involvement, when one still has time to nfirm the diagnosis by examination of the fluid d time to administer serum. It has been shown by yon [12] that cytolysis occurs in the cerebro-spinal uid if the fluid is allowed to stand after withdrawal, d that this cytolysis is selective, destroying the lymorphonuclear elements more rapidly than the ononuclear cells. For this reason and for the other at the treatment of preparalytic poliomyelitis is urgent matter, comparable to that of a ruptured topic gestation or intussusception, arrangements ould be made for examination of fluid at the bedside. he procedure adopted has been as follows :—

A careful clinical examination having failed to reveal y other cause for the illness, consideration of the gns and symptoms leading one to make a clinical agnosis of poliomyelitis, it is decided to carry out mbar puncture. The microscope and counting amber are placed in readiness, together with the agents for the Nonne-Apelt and Pandy's tests and luidin-blue solution. The needle is inserted, a w c.cm. of fluid are withdrawn, and the stillette is inserted and kept in position while the fluid is amined. If the cells be not increased the needle is en withdrawn. If the cells are increased, they are ained with toluidin-blue and the number of poly-orphonuclear and mononuclear cells counted. If e history has led to the suspicion of tuberculous eningitis, the chloride content of the fluid is esti-ated, for in poliomyelitis this is not reduced. If he fluid findings confirm the clinical diagnosis, the tillette is then withdrawn, fluid is allowed to escape, nd a slightly smaller quantity of warmed serum is lowly administered intrathecally by attachment of ubing and funnel to the lumbar puncture needle.

Thus the one anæsthetic which may be necessary n a child is sufficient for diagnostic lumbar puncture, ntrathecal and intravenous injections.

The findings in the cerebro-spinal fluid vary at different stages of the disease, and this variation is pathognomonic of preparalytic poliomyelitis. Early in the preparalytic stage the polymorphonuclear cells are increased, but they disappear as the lymphocytes increase until, at the stage of paralysis, only 5 per cent. to 10 per cent. of cells are polymorphonuclear. Globulin appears late in the preparalytic stage, and does not reach its highest concentration until paralysis has occurred, and it persists after the cell count has returned to normal. Details of the findings of the cerebro-spinal fluids examined will be found later in the case records (Table III.).

Dosage.

Increasing experience has impressed upon us the importance of an adequate initial dose of serum. By administration of a product containing proven viricidal properties, one attempts to give the patient a passive immunity, but the time factor is all important. Untreated, the majority of cases develop an immunity for themselves within the next few days; but during that period damage may be done to the nerve-cells which will alter the whole life of the patient. If therapy is to be effective, the virus must be inactivated by the viricidal properties of the serum and the disease cut short before the nerve-cells die. For this reason one cannot afford to delay between withdrawal of fluid and administration of serum while the fluid is sent to a laboratory for examination. Secondly, it appears unreasonable when the patient's future may depend on the race between development of passive immunity and the death of anterior horn cells, to administer serum intramuscularly or sub-cutaneously. Thirdly, it is imperative that the product used should possess as high a titre of viricidal properties as it is possible to obtain.

Aycock [14] and others [13] have demonstrated that serum of certain normal adults possesses viricidal properties, possibly developed during a subclinical infection. The only method of distinguishing those persons whose sera is so effective is by testing the power of individual specimens of sera to neutralise virus in vitro before innoculation of the serum-virus mixture into the brain of a monkey.

In most diseases the administration of inactive serum is not likely to cause positive harm; but in poliomyelitis the injection of inert serum may actually tend to promote paralysis. Flexner and Amoss [15] have shown that in monkeys who have received poliomyelitis virus intravenously, intranasally, or subcutaneously, the introduction of aseptic normal serum will promote invasion of the central nervous system. The condition of these monkeys is closely analogous to that of children in the preparalytic stage. Moreover, Schultz [16] has demonstrated that the time taken for immune serum to neutralise virus varies with the concentration of the serum—dilution delaying inactivation of virus. Our clinical experience has impressed upon us the brevity of the interval between the phase at which recognition of the disease is possible and the latest moment at which an injection of potent serum will avert paralysis. This fact, together with the reasons discussed—(1) the possibility of causing positive harm, (2) the certainty of delay in neutralisation of virus by dilution of any active serum which may be present by inert components—has led us to oppose the suggestion to use pooled normal human serum, of which the whole or part may be lacking in viricidal properties. By the after-care of all potential donors it has been possible to obtain adequate supplies of immune serum, and different epidemics in different localities. This step was taken after experimental work with monkeys by Burnet and Macnamara[4] which, within the limitations of the tests employed, indicated that serum from cases affected three to five years previously possessed viricidal properties equal to that of more recent cases In the course of this work evidence was obtained[5] that more than one strain of virus may exist which suggested the policy of pooling sera from many individuals.

During the period under review, 1925 to 1931, 83 persons have given blood in a total of 201 bleedings: 39 were bled once only; 11, twice; 17, three times; 8, four times; 3, five times; 1, six times; 2, seven times; and 2, nine times.

The time which elapsed between the onset of the disease and the withdrawal of blood for the preparation of serum was:—

	Instances.		Instances.
Under 1 year ..	86	Between—	
Between—		6 and 7 years ..	3
1 and 2 years ..	32	7 ,, 8 ,, ..	2
2 ,, 3 ,, ..	32	8 ,, 9 ,, ..	1
3 ,, 4 ,, ..	7	10 years and over ..	21
4 ,, 5 ,, ..	7		
5 ,, 6 ,, ..	10	Total	201

The product obtained has the following advantages. Though free from antiseptic, it can be stored at ice-box temperature and used with safety after several years, the viricidal properties being retained. A minimum of hæmolysis has occurred, and secondary formation of fibrin has been absent. In the literature[6] one reads of reactions occurring following the injection intravenously and intrathecally of human serum. In the 260 patients to whom serum has been administered in Victoria, no unpleasant reaction has occurred, and it is suggested that while the reason may be the freedom from hæmolysis and from added antiseptic, another explanation may be that removal of fibrinogen during clotting produced by the addition of calcium chloride is more complete than that which occurs when blood is allowed to clot naturally.

Use of Serum.

Victoria has an area of 87,884 square miles and a population of 1,777,065, of whom 1,036,630 live in the capital city, Melbourne. The incidence of poliomyelitis in Victoria since this work has been undertaken has been as follows:—

Total	873

In 1925 only one case was diagnosed before paralysis. Serum was administered to 12 patients after paralysis had been present for some days. These cases have been examined regularly, and their progress noted and compared with that of others with similar initial paralysis among the group of cases who did not receive serum. The degree and rate of recovery of power in the serum cases was no better than that of the controls who received identical after-treatment, and we soon realised that it was not justifiable to administer expensive serum to afebrile patients after paralysis had been present for some days. Education of the profession and the interest of the public resulted in an increase in the proportion of cases diagnosed before paralysis, until, in 1931, of 270 cases, 86 were treated in the preparalytic stage.

The Preparalytic Stage.

The type of case with fulminating onset has been exceedingly rare. The mode of onset has been either the straggling or dromedary types described by Draper.[7] In the former the illness has lasted from two to seven days; in the latter a period up to 14 days, which include an intermission of apparent recovery. The usual story in this type is one of two or three days' indefinite illness, fever, vomiting, drowsiness, and lassitude, then improvement for a period in which the child may resume attendance at school followed by a second phase of illness, which after 24–48 hours is followed by paralysis.

The syndrome of the preparalytic stage can be recognised. It varies slightly in different age-groups, in babies under 12 months, in children and in adults, in different epidemics, in different phases of one epidemic and in different parts of the country, but our experience has confirmed that of American[9] and New Zealand[10] observers—that it is possible to be reasonably certain of the diagnosis by clinical examination before seeking the confirmation of cerebro-spinal fluid findings. Fever is usually present; it is rarely high in the early weeks of an epidemic, though temperatures of 103°–104° F. often occur during the peak months. In adults the temperature may be no higher than 100° F. (37·8° C.). Headache is a common complaint of older children, and in adults may be severe. Drowsiness when left alone and irritability when disturbed is a common story of the parent, but the irritability has differed from that of children with meningitis. If time and patience and gentleness be given to the examination, and the child reassured, the usual finding is one of intelligent coöperation. Pain in the neck or between the shoulder-blades is frequent. Pain may be referred to a limb which will later become hyperæsthetic. Vomiting once has been the usual story. Convulsions rarely occur, and persistent convulsions suggest another diagnosis. Photophobia, retention of urine, localised sweating, tremor of the hands do not occur in every case, but any one of these symptoms is a valuable warning. Constipation is usual.

SPINE SIGN.

The most valuable sign has been the spine sign. By this is meant disinclination to flex the spine anteriorly because of the pain involved by the movement. Although spinal rigidity of a degree comparable to the opisthotonus of tetanus or cerebro-spinal meningitis may occur in preparalytic poliomyelitis, if one expects head retraction of that degree, the majority of cases will be missed.

The spine sign must be deliberately elicited. It is not wise to try to elicit it with the child in a recumbent position by placing the hand under the head and bringing the head forward. Almost any febrile child resents that handling. If the fever is not high, take the child from the bed, place him in the sitting position, or nurse him comfortably in the arms and gently persuade him to kiss his knee. The child attempts to carry out the movement and gives up "because it hurts" either at the back of the neck, between the shoulders, or in the hamstrings, or in some cases throughout the whole length of the back. In order to obtain his coöperation bribe him with a penny as a prize if the lips meet the knee. Even with help by passive movement, if a spine sign be present the child, though anxious for the penny, cannot earn it. In adults or in children when fever is high, carry out the test with the patient lying on his side, and passively flex the spine as far as the patient will allow. In babies, one has to rely on passive flexion in order to estimate the amount of pain caused by the movement.

Amoss's sign, though not invariably present, can often be elicited. When the child is placed in the sitting position on a firm chair or table, the position assumed is that of a tripod, the child using both arms to support part of the body-weight and to throw

THE LANCET COMMISSION ON NURSING.

(Continued from p. 417.)

HE second section of the Final Report is itled the

Evolution of British Nursing.

early history of nursing, from the institution of Deaconesses in the first century A.D. and the er of Women Clergy, the Widows, and Deaconesses gnised by the Church in the IVth and following turies, is traced through the mediæval develop- its to the phase when the military orders had r origin in the events of the Second Crusade. date of the foundation of the Knights Hospitallers St. John of Jerusalem is 1100, and an interesting er, the Béguines, was almost contemporary in its h at Liége. Many religious and secular Orders e in France, Italy, and Germany during the next e centuries, but the practice of nursing received ll impetus from them.

n the XVIIth century Vincent de Paul founded Sisters of Charity, but their functions were ricted, and a general decline in nursing marked XVIIth and XVIIIth centuries, the evil times g protracted until the middle of the XIXth tury. Nursing as a calling was at its lowest level the beginning of the XIXth century, nowhere ing shared in the general development of social nities. In 1822 the Kaiserswerth movement luded real advance.

t the beginning of the XIXth century there was no anised nursing in this country, and an awakening the public conscience did not come until some years after the Kaiserswerth example had been set.

Details are given in the Report of the plight of tain London hospitals at this time. Until as late 1840 many of the women hired to nurse in hospitals e given such low wages that no preliminary inquiry their character was convenient, and it is not prising that we read of charges brought against m of unchastity, drunkenness, bad language, and ering. The quality and quantity of their food- ply and their sleeping accommodation, when vided within the walls, was often disgraceful. s not the failings of women placed in such circum- nces that should be wondered at, but their virtues. e life of many of them was a record of self-sacrifice. ey could only render such help as they were npetent for, and in the dismal situation it is comfort- to recollect that the technique required of them s no more than the rendering of domestic duties in l and sometimes revolting circumstances. The ition of being regarded as a good nurse was attained en a woman, through experience, obtained a owledge of how to dress wounds and how to relieve n by suitable applications and by changes of sture. A certain number of nurses would learn to erpret symptomatic troubles, and so to gauge e seriousness of a case. The qualities of such women re perceived by the medical staff, but were other- se unrecognised. The depressing attitude of those ponsible for the management of the institutions s that, in such surroundings, only those nurses ed be expected whose standards were in accord th the environment.

Early efforts at reform are described, the institution the British Nursing Orders, and finally the grand volution in nursing that came with the Crimean War, and the modern developments of Florence Nightingale's pioneer work.

Modern Times.

These developments, says the final paragraph of this section of the Report, have produced a service of nursing working successfully in institutions from which every vestige of the ancient horrors has disappeared. But these horrors once existed, and certain of them could only have been eradicated by the presence of women who were known to have definitely renounced worldly aims, dedicating themselves to an austere life under rigid discipline, the discipline being enjoined partly at least to protect young women from slander and to satisfy parents of their safety. Their submission to or acceptance of the strict conditions laid down had a productive result, for standards of decency and of equipment in hospitals were quickly raised. All this must be remembered when the traditional hospital training is criticised. If the machinery has been altered too slowly to correspond with modern requirements, its pattern was at one time admirably appropriate, even essential, to the work which had to be done. It is because the impetus towards an exclusively vocational ideal has been so fervent and so lasting, that even now some hold the outlook of the young professional woman of these times to be incompatible with the practice of nursing.

To-day, with the progress of medicine, the degree of coöperation required by the doctor from the nurse has increased, and has made necessary certain changes bringing with them a need of developing qualities of discretion, resourcefulness, and scientific observation in the student nurse. Experience has shown that these may be cultivated without sacrifice of the vocational ideal, though the discipline which fosters them may be of a somewhat different order than that enjoined by tradition.

The whole of Section III. of the Report on the present position of nursing is set out in full below.

The Present Position.

The establishment in 1919 of the General Nursing Councils gave nursing a definite professional status. Certain hospitals only were approved as training schools, and a standard curriculum was instituted, leading up to examinations for admission to State registers. Unfortunately these developments have not been effective in increasing the popularity of nursing as a profession for educated women, although, during the last 12 years, other professions and occupations open to women have become increasingly crowded.

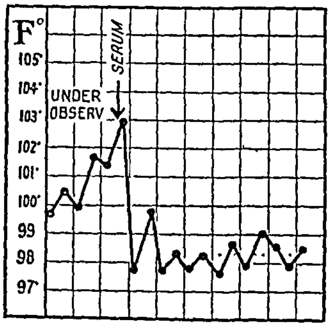
THE BARRIER TO COÖPERATION.

The nurse's conditions of training and service have fallen into relative disfavour not only with young people in search of a career, but also with their advisers, and with women in other professions. On the other hand, nurses themselves are distressed and even indignant at what they regard as an undeserved prejudice against hospital life.

The nursing profession as a whole tends to view the conditions of service and training now available in the light of those offered in the past, even as recently as ten years ago, and finds them immeasurably more favourable; whereas women in other professions, and girls debating their future career, are apt to brush aside as irrelevant any description of past conditions, and to survey hospital life as it actually is to-day, detached from its background of fine tradition. The divergence of outlook forms a barrier, the more formidable because it has not been openly acknowledged, therefore it has not been necessary to carry out the preliminary testing of specimens of normal sera which alone would justify its use.

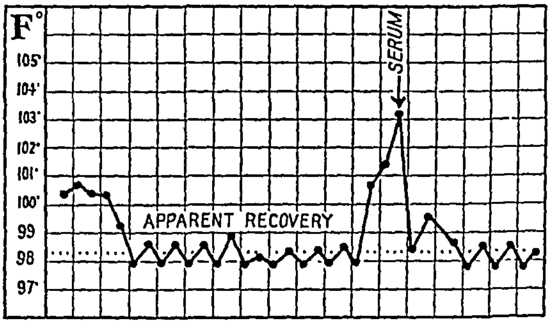
In estimating the dose of serum required, one takes into consideration the following points: the age and size of the patient, the degree of toxæmia, the stage of the epidemic, and the duration of his illness, particularly the duration of the signs of meningeal involvement and the cerebro-spinal fluid findings. A patient in whom a history is obtained of illness eight to four days previously, followed by an interval of apparent recovery lasting for two to three days, followed by the second phase of his illness with pain in the neck and back, fever, and a spine sign lasting over 24 hours, has little time to lose. The development of tremor and hyperæsthesia suggests that already some involvement of motor cells and sensory ganglia has occurred. These symptoms call for a larger dose than that which should be given to a patient who has developed a spine sign within the last six hours after two days of observation.

FIG. 1.



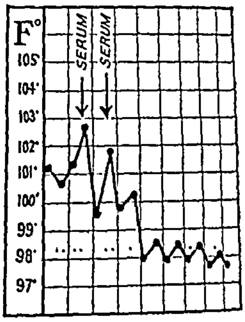
Satisfactory response to injection of serum.

FIG. 2.



Dromedary type of onset. Satisfactory response to injection of serum.

FIG. 3.



Unsatisfactory response to first injection. Second dose was required and given. Response was satisfactory.

The type of cell found in the fluid is of assistance in estimating the dose required. When almost all the cells are lymphocytes, paralysis is not far off, and therefore the dose should be increased.

The initial dose of serum used has been rarely less than 50 c.cm. After the cerebro-spinal fluid has been allowed to escape, a slightly smaller quantity of serum is administered intrathecally, and the remainder of the dose administered intravenously, even though venesection may be necessary. The patient should be carefully re-examined 12, 18, and 24 hours later. If the dose has been adequate, though spinal rigidity will persist, the temperature should have fallen, and the general condition be greatly improved (Figs. 1 and 2). During the interval other confusing factors should be eliminated. These patients are usually constipated, dehydrated, and slightly acidotic, the pain in the neck having prevented ingestion of fluid. After administration of serum, a brisk aperient should be given, and carbohydrate and fluid administered freely by means of a spoon or bent glass tube or feeding-cup, which will save the patient the discomfort of flexion of the neck.

If improvement is not marked within 18 hours, we have considered that an insufficient dose has been given, and a further 30 to 40 c.cm. has been injected intravenously (Fig. 3). The failures in the series have taught us the importance of this examination 12, 18, and 24 hours after the first, and have influenced us in omitting antiseptic from the serum. If, 12 to 18 hours after injection of a product containing antiseptic, fibrinogen, or hæmolysed red cells, the temperature is still elevated, the patient still miserable, complaining of headache, perhaps vomiting, one cannot estimate how much to attribute to reaction to the therapy and how much is due to insufficient dosage. The use of a non-irritating serum does not cause confusion at this important stage. In our series, if the patient had not improved within 20 hours, there has been one reason only—insufficient dosage.

While experimental work on the production of immune sera by the inoculation of horses with filtrates and suspensions of the spinal cords of monkeys infected by poliomyelitis virus[17] may in the future lead to the production of serum of therapeutic value, it would appear that the reactions at present induced by injections of horse serum are, in this disease, a serious disadvantage.

(To be continued.)

SUSSEX PROVIDENT SCHEME.—The sum of £17,537 was distributed among the coöperating hospitals under this scheme during 1931. Inaugurated in 1921, when only £332 was distributed, the amount has increased each year, and local hospitals have received over £90,000. In the allocation for 1931, the Royal Sussex County Hospital, Brighton, received £6806; the Royal Alexandra Hospital for Sick Children, Brighton, £2199; the New Sussex Hospital, £1554; and Hove Hospital, £1052. Other substantial allocations included Haywards Heath Hospital, £981; Sussex Eye Hospital, £804; and Brighton Corporation, £662. Twenty-two other hospitals and kindred organisations as far afield as Hastings and St. Leonards, Horsham, and Arundel and Littlehampton also participated.

Fortunately, many matrons of important institutions now belong to this category, and they are doing much to bring hospital training into line with other forms of training; but their efforts are often hampered by the conservative attitude of valued members of their senior staffs. Ward sisters, especially those who have given their lives to hospital service without seeking administrative promotion, may be intolerant of attempts to induce them to allow to others a discipline less severe than that which they willingly impose on themselves. Their conception of vocation is high and rigid, and their attitude to the probationer is biased by their anxiety to preserve for the service of the hospital the whole of her available strength, vitality, and self-minded interest.

CRITICISM FROM WITHIN.

We have been fortunate in obtaining evidence on the training conditions in hospital from women who have reached high positions in the nursing world, after having previously trained for other professions. Their comments are illuminating, since they support those which have reached us from women's organisations outside the profession of nursing, such as the National Council of Women, the London and National Society for Women's Service, and the Association of Headmistresses. These comments may be summed up in the conclusion that the shortage of educated candidates is definitely related to the conditions of training offered by the hospitals, which are not even now catering intelligently for the type which they seek to enlist. The reference is not only, or even primarily, to conditions which have an economic basis, such as uncomfortable quarters or indifferent food, though reports of such conditions have a deterrent effect far beyond the range of the particular hospital guilty of such short-sighted negligence. The anomalies which especially worry the most desirable young nurse and her friends may coexist with a luxurious Nurses' Home and an excellent dietary.

RESPONSIBILITY WITHOUT TRUST.

The most noticeable of these anomalies, and one which really includes all the rest, is the contrast between the degree of responsibility assigned to the probationer in the wards and the degree of confidence reposed in her in the Nurses' Home. While still a student she may be left at night in sole charge of a ward of sick people, or be detailed to wash, tend, and report on the changing condition of a critically ill patient. Though she is given such serious and responsible duties, the amount of discretion allowed her in the conduct of her personal affairs, that is, in the organisation of that part of the 24 hours when she is not on duty, is very small. For example, she is usually obliged to attend all the principal meals, even when they are adjacent to off-duty hours. She must be in her room at 10 P.M. and her lights must be out at 10.30 P.M. She may not, as a rule, leave the hospital between 8 P.M., when she comes off duty, and bedtime, except by special permission. The reasons generally given for such restrictions are that the matron is responsible to the probationer's parents for seeing that she gets sufficient rest and food, and that her evenings are devoted to study. This degree of supervision was doubtless welcomed by parents when it corresponded closely with that exercised in middle-class homes; but we have ample evidence that it can no longer be held to reflect their wishes.

In any case, the fact that in most hospitals the same regulations are applied even to nurses no longer in training suggests that considerations other than a responsibility for the young beginner are involved. It is not disputed by anyone that in view of the long span of the nurse's working day, and of the arduous nature of her duties, she must, if breakdown is to be avoided, lead a life more regular and austere than need be adopted by those doing other work. The change in outlook that hospital authorities have not yet recognised is that the modern girl does not admit the propriety of any attempt to ensure her efficiency as an employee by regulation of her private life. If she cares to miss an occasional meal, or to spend her evenings at her home or at some entertainment, or to read late, it is her own business; if she is unpunctual at her work, or slack in the performance of her duties, her employers have an easy remedy in a threat of dismissal. But it is for her, she holds, and not for them to regulate her life in accordance with the work she has undertaken, and the assumption that she needs protective supervision she finds quite unacceptable.

THE TRADITIONAL OUTLOOK AND THE MODERN OUTLOOK.

It is clear that basic differences between the traditional and the modern outlook on women's work and aspirations have here to be recognised and reconciled. It has been suggested to us that differentiation between the regulations applying to trained and to untrained staff in hospitals might provide a useful, though possibly only a temporary, bridge between the two outlooks. If the prospect of escaping from a protective environment after State registration encouraged educated girls to enter hospitals, the emancipation of probationers would follow. At present the fear that they will be treated as children deters well-educated girls from taking up nursing. But until a better type of candidate presents herself, it is not surprising that the hospitals should continue to treat probationers as children, since many of them have not been trained to self-government before entering hospital. When after three years this training is completed, however, and the nurse is deemed fit to be sent out into the world as a State-registered nurse, she should also be fit to be trusted to regulate her own life in hospital outside working hours. Action which indicated acceptance of this point of view might do more, perhaps, than any other single step to re-establish confidence between women within and without the hospitals, and might serve to secure the coöperation of all sections of the community in attempts to restore nursing to its former position in the esteem of educated women. *(To be continued.)*

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

VACCINATION IN VIENNA.

IN this country vaccination against small-pox is not strictly compulsory, but indirect coercion is exercised by regulations which stipulate that eligibility for certain appointments or situations, admission to all kinds of higher schools or institutions, to official posts, and to public offices, and even the award of prizes is dependent on production of a certificate of successful vaccination. When there is an epidemic of small-pox revaccination and primary vaccination may be enforced by an "ambulant vaccination officer" (Public Health Act of 1840). In a publication by the Vienna Board of Health, covering the last ten years (1919–1929) some interesting figures are given relating to first vaccinations and vaccination in schools. In 1919, 42,197 persons were reported which hampers free discussion between those within and those without the profession, and which must be broken down before sympathetic coöperation can be achieved. An atmosphere of tension and mutual misunderstanding has therefore grown up which it is difficult to dispel by argument.

MISCONCEPTIONS ON BOTH SIDES.

It is probably true that the prejudice against nursing which is undoubtedly present in the minds of parents, schoolmistresses, and young girls, is partly based on ignorance of the improvements which have been made in the conditions, accommodation, and amenities now offered to probationers in the best training hospitals. There is still a widespread belief that nurses in training are worked excessively hard, are allowed no freedom, are subject to unduly severe discipline. and are neither fed well nor lodged comfortably. A girl to whom nursing is proposed as a career envisages a period of three years at least of drudgery, during which time she will be cut off from her friends, her games, and her social amusements, will be always overtired physically, and often snubbed and reproved. Reiterated assurances that this dark picture no longer represents—if it ever did represent—hospital life do not serve to obliterate it. It will fade completely only when it is patently untrue to life in every hospital in the country, for its colours are constantly being revived by reports from probationers who have not been fortunate in their selection of a training school. Further, general recognition of improvements in conditions has been delayed not only by a lack of uniformity in their adoption, but also by a reluctance on the part of hospitals to give wide publicity to such changes, with the implied admission that they were necessary or even overdue. It is therefore not remarkable that misconceptions still obtain. The clear picture of present-day hospital life provided by our Second Interim Report (see Appendix XVIII.) should do much to remove them. It also shows that the conditions which gave rise to prejudice in the past have not been wholly eliminated.

"WHAT MORE DO THEY WANT?"

Senior nurses who have watched with amazement, and not always with approval, the improvement in the conditions offered to probationers during recent years, express themselves at a loss to understand why girls are not attracted to this work in large numbers. When faced with a shortage they ask: "What more do they want?" The recital of what they do want, or what their parents, headmistresses, or sisters in other professions want for them, is, however, likely to be coldly received. It may even be resented as criticism of a system which tradition has made sacred, and which has admittedly produced nurses unsurpassed throughout the world for perception, skill, and sense of responsibility.

How can a better understanding be brought about? The first essential is a candid exploration of the issues involved, and a determination to find common ground. The basis of this common ground must be the recognition on both sides that while a professional organisation has been superimposed on a system of apprenticeship, this system is valued not only because it is sanctioned by tradition, but for its own sake.

THE VALUE PLACED ON ROUTINE.

The element of apprenticeship is regarded by most of the leaders of the nursing profession, at least in this country, as a far more important part of a nurse's training than her theoretical studies. Some senior nurses, notably ward sisters, may still be heard to protest that the vocational spirit which inspired former generations of nurses has been dimmed by the introduction of a standard curriculum. Although most of them are now beginning to realise that their early fears in this respect were unfounded, they attribute the preservation of the vocational spirit to the retention of a factor in hospital life which has been severely criticised from outside the profession, and is stated to have prevented many girls from entering hospitals. This factor is the routine work of the probationer, occupying nine to ten hours a day. It has not been modified to give her more time and leisure for study; and though the passing of State examinations is now essential to her career, she must fit in her theoretical work and at least some of her lectures during her official off-duty time.

Women in other professions are apt to regard such long hours of routine work, the restrictions on liberty when off duty, in short, the scanty opportunity given to the nurse in training to lead a normal social life and to cultivate interests apart from her work, as being associated mainly with the desire of the hospitals to economise at the expense of their staff. They criticise senior nurses for acquiescing without protest in a system which admits of the exploitation of student labour. But they fail to recognise that a large section of the nursing profession, especially ward sisters, remain convinced of the value of a strict discipline, which is designed to plant and foster in the probationer certain qualities and habits. Among these are uncritical obedience; punctuality; loyalty to superiors and to the institution served; together with a sense of responsibility and of vocation which, in the opinion of many, is incompatible with the cultivation and maintenance of wide interests outside the hospital community.

A CONFLICT OF IDEALS.

It is this attitude which underlies the disregard of the mental conflict that may trouble a probationer who comes from a good secondary school; there her duty has been primarily to learn, her critical faculty has been stimulated, and her practical work has been assessed for precision and neatness and a grasp of principle, rather than for a speed of execution which to a beginner is incompatible with a high standard of efficiency. She soon learns in hospital that her first duty is to help to get the work done, and in some hospitals she must also learn to subdue her critical impulses and even her curiosity. It is assumed that she will never make a good nurse unless she regards her time as the hospital's and not her own, and her training as incidental to the work she does as employee. A receptive young nurse soon absorbs this spirit, and is in her turn shocked at the solecisms and breaches of etiquette committed by newcomers. But in the process of acclimatisation she is liable to adopt blindly the traditions of her seniors—the reaction has been aptly described as "putting on the blinkers"—and to become as impervious as they are to the fact that the educational methods practised in hospitals have been largely superseded elsewhere by methods which rely on arousing, instead of damping, curiosity and initiative, and which insist on the importance of developing a student's personality and tastes outside the range of daily work.

It is only the exceptional nurse, that is, one who has maintained close touch with the social and educational tendencies of the day, who is able to discern which of the peculiarities of hospital life are essential to its structure, and which are mere survivals from a different age, and could safely be jettisoned.

best gladiatorial spirit. The esteem in which one side is held by the other can, perhaps, be measured in less vivid terms than was the case only a few generations ago; but there still remains a strong tendency to score debating points rather than more solid advantages. This correspondence might, in fact, have ended in the usual stalemate, had not a practical suggestion been made by a doctor holding a hospital appointment. Dr. Weismann-Netter, of the Saint-Antoine Hospital, has invited his homœopath colleagues to treat patients in his hospital, his only stipulation being that the guests contribute the same good faith to the proposed tests that the host himself guarantees. In this way he hopes to test such homœopathic claims as that Jenner's vaccine, given by the mouth in homœopathic doses, confers specific immunity on the person concerned; and that a Wassermann reaction which has hitherto persisted in being positive, becomes negative on the administration of the homœopathic "syphilinum." Assuredly this invitation is bona fide. Will it be accepted? A year or two hence we may, perhaps, have some interesting results to report.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

SCHOOL VENTILATION.

THE publication of the final report of the New York Commission on Ventilation [1] is an event of significance partly because of the great amount of research which lies behind it and partly because of the strenuous protests that the earlier conclusions of the distinguished committee have aroused. Ventilating engineers have loudly demanded definite specifications for construction. The committee has throughout preferred to stress desirable conditions of temperature, humidity, and air movement. In an earlier report they had, however, concluded that "window gravity ventilation is definitely superior to plenum ventilation." This conclusion, all the more startling since several of the States had written "plenum" into their school building codes, raised a storm of indignation among the engineers and is now definitely withdrawn. "Desirable air conditions," the present report states, "may be obtained . . . (*a*) by plenum ventilation; (*b*) by local unit ventilation; (*c*) by window gravity ventilation."

The commission recommends a model law as follows:

1. The major objectives of schoolroom ventilation shall be the elimination of heat from the body surface without the production of objectionable draughts. This means the maintainance of a room temperature of 65° F. in corridors, gymnasiums, and shops; of 75° F. in swimming pools and adjacent dressing rooms; and of 68° F. in all other occupied rooms.

2. The avoidance of overheating is of primary importance for the promotion of comfort and efficiency, and the maintenance of resistance against disease. Sources of direct radiation, therefore, shall be so designed or protected as to prevent overheating of persons in adjacent seats.

3. All classrooms shall have at least 15 square feet of floor space and 200 cubic feet of air space per pupil, and shall have a system of heating and ventilation which shall provide means of air supply and exhaust capable of avoiding unpleasant odours, and of avoiding, without chilling draughts, an increase of room temperature above 68° F.

4. Such ventilation shall be accomplished by any means which will attain satisfactorily these specified results. For the average school, favourably located, window gravity (open window) ventilation seems to be the method of choice on grounds of comfort and economy.

5. Every schoolroom used for instruction, study, assembly, and physical recreation shall be provided with at least one thermometer of a grade that will give a reading accurate to within one degree F. The thermometer should be so located as to give a representative reading of temperature at the breathing plane of the pupils.

Engineers would be required to submit for approval by either the State Board of Education or the State Board of Health plans which in their judgment would provide the above conditions. Such an arrangement, the commission points out, is on all fours with present regulations governing water-supply and waste disposal.

This 1931 report should be read as an addendum to the exhaustive report published in 1923.

FEDERAL GRANTS IN AID OF HEALTH WORK.

The old battle concerning Federal subsidy to the States for health which ended in 1929 with the lapsing of the Sheppard-Towner Maternity and Infancy Act of 1921 is about to be resumed in Congress. Three Bills have been introduced which substantially renew the conditions of the former Act, but add thereto provisions for subsidies in aid of schemes for rural public health work which must be approved by a "Federal Health Coördinating Board." In the lobby for these Bills will be the powerful organisations of the women voters as well as the State health authorities. In the opposite lobby is found the medical profession, or at least its articulate representatives, with many arguments [2] inspired by the fear of that monster "State medicine" before the thought of which almost all American physicians still recoil in horror. The main chance of defeating the Bills lies in the present need for national economy. H.R. 7525, introduced by Representative Bankhead of Alabama, having been recommended in committee, is already on the calendar of the House of Representatives. It calls for appropriations increasing from two and a quarter million dollars in the present year to four and a quarter million dollars in 1937 and subsequent years. This is a small sum in comparison with demands made by other Bills for unemployment relief and naval replacements, and yet the President's appeal for stringent economy will have to be considered.

As regards the success of the old Sheppard-Towner Act, Miss Grace Abbott, chief of the Children's Bureau, states that "no State department of health developed what could be called a maternal hygiene programme until after the passage of the Maternity and Infancy Act in November, 1921. At the time when the benefits of the Act came to an end on June 30th, 1929, every State except Vermont had such a division or bureau functioning in the field of maternal and child hygiene and the Department of Health of Vermont . . . had inaugurated an educational programme in maternal and child care." In contrast to this statement place that found in the editorial above mentioned, "A considerable number of states did not appropriate for maternal hygiene up to their full financial ability until after the repeal of the Sheppard-Towner Act. Apparently federal aid has a deadening effect on State initiative!" Miss Abbott gives in detail statistics for the registration states of 1921 showing a decline in infant mortality from 75·0 in 1921 to 65·7 in 1929, and of maternal mortality from 67·3 (per 10,000 live births) in 1921 to 63·7 in 1929. The editorial in the Journal of the American Medical Association, though it gives no statistics, states that the operation of the Act "did not accelerate the rate of decline in either the maternal or the infant death-rates by even a fraction of a point per annum." And so the battle is waged.

---

[1] School Ventilation: Principles and Practices. Pub. Bureau of Publications, Teachers' College, Columbia University, N.Y.C. 1931. Pp. 67. $1.

[2] See editorial, Jour. Amer. Med. Assoc., Jan. 30th, p. 401.

by the medical practitioners and by the public vaccinators as having applied for vaccination. Of these, 9165 were vaccinated for the first time, and 17,544 were school-children. The figures for the following years are as follows :—

Year.	Total vaccinated.	First vaccinations, including school-children.	Vaccination of school-children, including revaccination.
1920 ..	38,691	8,993	18,329
1921 ..	41,890	8,291	28,681
1923 ..	44,483	10,240	28,293
1924 ..	38,836	10,569	22,668
1925 ..	28,110	11,103	20,293
1926 ..	28,079	14,960	25,712
1927 ..	33,304	15,110	24,548
1929 ..	44,113	17,958	28,114

The figures for the years 1922 and 1928 are not included in this compilation, for they require confirmation. But it is quite clear that during the last few years almost the entire population of this city may be regarded as being under the effect of prophylactic vaccination. The result is that for some four years there has not been a single case of small-pox in Vienna.

THE TITLE OF SPECIALIST.

In a report presented to the Vienna Aerztekammer (medical board), Dr. Sonnenfeld discusses the present state of regulations concerning the title of "Facharzt" or specialist. It is perhaps surprising that at present there is no legal definition. Any medical man may call himself a specialist in any particular branch of medicine or surgery he chooses. Only, if he wants to take part in contract practice, as arranged between the sick-clubs and the representative board of the medical profession (Wirthschaftliche Organisation der Aerzte), he must comply with the regulations and submit to the restrictions arranged between these two parties. A would-be specialist must show proof that he has studied for at least four years, after graduation as M.D., in an institution or clinic devoted solely to his specialty. Then he must become a member of one of the 14 groups of specialists dealing with surgery, dermatology, gynæcology (including obstetrics), internal medicine, respiratory disease, neurology and psychiatry, ophthalmology, orthopædics, oto-rhino-laryngology, pædiatrics, physico-therapeutics, röntgenology, urology, and medical laboratory work. For the surgical branches, the applicant should show evidence of post-graduate study for not less than five years, and he must satisfy the board that he has been working quite independently —i.e., as fully qualified assistant or locum tenent in the special wards or departments. This holds good for Vienna. In the provinces the applicant for the title of specialist must satisfy the official medical board of his specialist studies, if he wishes to take part in contract practice. Otherwise he is bound in no way to any consent on the part of medical corporations or bodies. In Vienna, the specialist may only practise in one of the 14 above-mentioned groups; in the provinces he may combine two or more groups. But, I repeat, this is only a private arrangement between the two organisations. Even in Vienna a man restricting himself to private practice may combine whatever specialties he wishes. The public, however, is so used to regarding only the properly qualified man as Facharzt that in practice the regulations sketched above are valid for all specialists, for there are hardly any medical men practising who do not, in one way or other, come under the scope of the contract arrangement mentioned before. Only for one group of specialists do we provide legal protection—namely, dental surgeons. The title of Zahnarzt may be used only by a duly qualified medical man, who, after having taken his M.D. degree, has worked for two years in the dental clinic and restricts his practice to the diseases of the teeth and mouth arising from dental troubles. At present there are in Vienna about 1200 specialists and 600 dental surgeons, out of a total of about 3600 practitioners.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

BURIAL OF THE APPARENTLY DEAD.

A YEAR ago the Chamber of Deputies asked the Government to take the advice of the Academies of Medicine and Sciences in connexion with a reliable test of death, whose use would reduce to a minimum the number of premature burials. A commission of experts was appointed to deal with this matter, and on Feb. 2nd their report was presented to the Academy of Medicine. In the opinion of the members the risks of burial alive have been exaggerated, but in times of stress, war, epidemics, and the like, mistakes have been made, and whether the public's fear of premature burial be justified or not, the fact remains that this fear exists. Everything possible should therefore be done to remove not only the danger itself, but also the fear of it. The cases of mistaken death include those of hysterical lethargy in which general paralysis and anæsthesia are associated with retention of sensory perceptions. As circulation and respiration continue, the trained medical observer should not go astray. In other cases, under the influence of nervous shock, a condition arises similar to that of hibernating animals. This condition may end in death if energetic measures are not taken, and as it has been drily remarked, it is less important to make the diagnosis of death in such cases than to consider the prognosis and act accordingly. Syncope, again, is a condition in which a mistaken diagnosis of death may prove fatal, whether the patients have been hanged, drowned, gassed by carbon monoxide, poisoned by chloroform, or electrocuted. In the last-named state, syncope has been known to last for more than two hours. After describing the various tests and signs of death, and noting that little is yet known of Icard's test (intravenous injection of fluorescein, which discolours the conjunctivæ if blood is still circulating in the body) in connexion with the syncope of electrocution, the commission concludes that, after all, the most reliable sign of death is bleeding from a severed radial artery. The three main recommendations of the commission are (1) to wait at least 24 hours after death before burial, (2) not to bury anyone without a medical examination of the defunct, and (3) to put this medical examination, at any rate in the large towns, in the charge of doctors who have mastered the technique of the modern scientific tests of death. The commission envisages a system, according to which every person who is supposed to have died will be carefully examined for signs of respiration, circulation, &c., and the first manifestations of putrefaction, the doctor returning several hours later if he is in the slightest doubt.

HOMŒOPATH AND ALLOPATH.

The already lively pages of the *Siècle Médical* have recently been given an additional attraction by a homœopath-allopath correspondence conducted in the oy if he had been attended weekly by the doctor; hey replied that he had been seen weekly and hat they had no complaint to make. The regional fficer gave this unprejudiced evidence before the ommittee and the charge of wrongful certification was held not to be established.

An approved society complained that a National Health official certificate had been filled up incorrectly. The principal's assistant attended the patient's onfinement on August 16th, and he issued an intermediate certificate on August 19th, giving the cause of ncapacity as pregnancy. The doctor said this was written by mistake for puerperium. The giving of ny intermediate certificate was incorrect apart rom the clerical error. Sickness benefit ceases on confinement and the patient by her certificate of confinement becomes automatically entitled to four weeks maternity benefit and only after that time does sickness benefit begin again by the issue of a first certificate if the patient is still considered incapable of work. This doctor did not use the argument that as pregnancy was the cause of the confinement it was a correct term to use. Pregnancy is, however, a very well-known condition to lay people and it can hardly be correct to say that a woman is pregnant one week after her confinement. The matter is important to approved societies, for it may enable a patient to get sickness and maternity benefit at the same time unless great care is exercised in the supervision of certificates. The doctor was found guilty of a breach of the certification rules and was warned.

A patient visiting London consulted an insurance practitioner but did not claim treatment as an insured person. During the course of this treatment the doctor issued two National Health Insurance certificates, and at the end he submitted a private account, whereas official certificates must not be issued to patients who are being treated privately. The doctor agreed to withdraw the account and the committee accepted the statement that he had acted in good faith.

RECORDS.

Insurance practitioners are required under the terms of service to keep accurate records of work done on behalf of panel patients by entering details with clinical notes on the particular envelope (FMR), that belongs to each patient. Special payment for this clerical work was granted and included in the present capitation fee. This work is important in that proper notes help the doctor in the treatment of the case and are helpful to the next doctor attending should the patient move to another area. Moreover these entries provide statistics on which negotiations take place for the capitation fee. If no entries are made on these envelopes it appears that less work is being done than is really the case and it supports the argument that doctors are being overpaid for the work they do. An insurance practitioner was visited by a regional medical officer twice. On the first occasion there was no entry on 100 medical record envelopes (FMR); he was warned, and revisited some few months later when 549 cards had no entry from the period Feb. 15th to August 14th, 1931. The visitor asked the doctor to appear before his officers or write to say what explanation he had to offer but he did not write or appear. The sum of £5 was deducted from his next cheque.

AN ALLEGATION OF NEGLECT.

This case illustrates the necessity of straightforward dealing by a patient with his doctor or by the relatives when a doctor is attending. The mother of the deceased patient—a boy—failed to inform the doctor, when he called, either that a nurse had been called in to see the boy or that she had taken the boy's temperature and found it to be 104° F. The mother brought a charge of neglecting treatment in this case and she made allegations of drunkenness also against the doctor. The boy was sent to hospital by another doctor where he died from pneumonia. The mother's evidence was found to be unreliable in the matter of medicines, for she said only one bottle was given whereas the prescriptions which were dispensed showed he had had three bottles. The doctor was given the benefit of the doubt largely on the unreliability of the mother's evidence, but although the committee were satisfied that he was never in an intoxicated condition, a bad impression was created when it was admitted that he walked into the house and even into the bedroom smoking and he was advised when attending an ill patient, who (he said) was alone, to write down instructions that he wished carried out and not to leave it to the patient to remember to give to relatives when they returned.

CHARGING A FEE.

A mistress asked a doctor to see her maid and at the end of the consultation the maid handed her medical card to the doctor indicating thus that she was an insured person and therefore entitled to free treatment. Nevertheless the doctor charged 5s. He explained that he had given the consultation before the card was handed to him and that as the mistress had asked for the consultation she would pay the fee. Regulations provide that patients who (1) say they are insured or (2) who present a medical card (which is not signed by a doctor living within two miles) cannot be charged unless at the same time an official receipt is given which when forwarded to the insurance committee within 14 days enables them to obtain a refund if the insurance committee are satisfied they are entitled to free treatment. No receipt was tendered in this case. The medical service subcommittee is apt to deal severely with fee-snatching; but in this case it was satisfied that the doctor acted under a genuine misapprehension and he was only warned that it must not occur again.

SIZE OF PANEL.

Single-handed doctors are not permitted to be paid for more than 2500 panel patients. To receive payment for numbers over 2500, a doctor must employ a whole-time assistant and obtain the consent of the insurance committee. This doctor, having more than 2500 patients, with the consent of the committee engaged a whole-time assistant. The assistant subsequently left his service and the doctor was without an assistant from June 1st to Sept. 30th. He was only paid for 2500 patients for the quarter July to September and the committee decided to deduct £5 from his remuneration, representing the excess over 2500 for whom he had been paid for the month of June.

HOSPITAL COSTS.—In the last year of the guardians control the cost of the general hospital at Newcastle-on-Tyne was £43,258; the cost for the year ending March 31st, the first under civic control, is estimated at £52,700, which includes £6900 for special items mainly connected with the change-over. For the year ending March 31st, 1930, the medical staff numbered 10 (5 part time and 5 full time), for the current year the number is 18 (10 part time and 8 full time). The salaries have increased from £1789 to £3810. The average number of patients was 520 in 1930, and 526 for the current year. Last year Malmesbury cottage hospital admitted 370 patients, the weekly cost of whose maintenance averaged £2 10s., against £2 13s. 6d. in the previous year. At the Clayton Hospital, Wakefield, the average weekly cost (1969 patients) was £2 8s. 4d.

PANEL AND CONTRACT PRACTICE

Partners and Assistants.

NEWLY qualified men entering general practice should be aware of differences in the regulations under the Insurance Act for partners and assistants. For instance, whereas two partners may have a total of 5000 patients on their list, and one of them may have 3000 patients, a principal and assistant may only have 4000 patients. A partner to be recognised as such must receive at least one-third of the share of any other partner; when so recognised he can deputise for any other partner without the patient being able to demand the personal services of his own doctor. This is not so with an assistant. Here the patient can demand the personal service of the principal, which if available he must give, unless he has a reasonable explanation for his omission. In either case continuity of treatment must be provided. Again the principal must obtain the consent of the insurance committee for the employment of an assistant, but not to take in a partner. This consent which is only given from year to year cannot as the phrase runs "be unreasonably withheld"; if withheld the insurance committee must consult the panel committee, and in the event of disagreement the principal has the right of appeal to the Minister. Permission would not be given to employ more than one assistant without the consent of the Ministry.

THE PRINCIPAL'S RESPONSIBILITY.

For all the acts of his assistant the principal is responsible, and the insurance committee requires the assistant to join the panel list, so that he can be dealt with if necessary under the disciplinary machinery; but this does not prevent the principal from entering into an agreement of the usual restrictive type dealing with notice, payment, and the question of accepting insured persons on the list in his own name. Since an assistant may leave, depending upon the agreement (if any), at a week's, or a month's, or possibly a quarter's notice, has no capital in the practice, and usually receives a fixed salary, it is unusual for a principal to allow, or for an insurance committee to encourage, an assistant to accept names of patients on his own list, even if, under his agreement with his principal, he has to make arrangements for them to change upon his leaving the practice. In this event, each patient would have to receive a notice from the insurance committee instructing him that Dr. A. was leaving, and that if he desired to change to another doctor he would have one month in which to do so; whereas, if all patients are accepted in the principal's name, no notice of change would have been required at all. Against this is the personal service difficulty. If all patients are on the list of the principal he is held responsible for personal service, and if it is found on an inspection of the prescriptions issued by the practice that only (say) 10 per cent. of these prescriptions are signed by the principal, and 90 per cent. by the assistant, the insurance committee might maintain that the principal is not giving his patients the personal service to which they are entitled. The case being brought before the medical service subcommittee, this argument may be used for refusing permission to employ an assistant when the application next arises.

WHAT IS FARMING-OUT?

It is suggested this is farming-out of practice. No one would defend the real farmer-out of practices to young medical men, in which the younger man does all the work and the principal takes the bulk of the income; especially when as too often happens the junior, misled by promises, finds himself embarrassed later by heavy annual payments for the purchase of a practice of his own making. In such bargains the payment for rent and goodwill are apt far to exceed the normal. Farming-out, moreover, is not likely to occur with one assistant and cases in which more than one assistant is employed are rare. Judging from decisions of the Ministry, the practice of allowing the assistant to do the bulk of the contract work *of a practice is not now* held to constitute farming-out. The assistant gains experience under the supervision of an experienced man, who is responsible for all his errors and has to make certain of continuity in treatment. Many newly qualified assistants, it is true, *are more* efficient in the diagnosis and treatment of disease than the principals who employ them, but they have not had experience of the general problems of practice.

INTERPRETATION OF "PERSONAL SERVICE."

These considerations are relevant to a case recently before the London Insurance Committee in which an elderly practitioner, carrying on the practice of a deceased friend until that friend's son and daughter should have qualified, acted as principal in the practice, *almost gratuitously*, but with the help of a very able assistant paid by fixed salary. The elderly practitioner has been refused permission to continue to employ an assistant on the ground that examination of the prescriptions issued shows him *to be attending to* only a very small amount of the panel work. Meanwhile the assistant is doing the bulk of this work admittedly to the satisfaction of the patients who always ask for him. And there have been no complaints. The case has been referred by the insurance committee to the panel committee for consultation, and should they disagree the Minister will presumably be asked to decide.

Pitfalls of Practice.

A SAMPLE OF COMPLAINTS.

A recent report of the medical service subcommittee for London gives an account of some more[1] of the pitfalls into which insurance practitioners are apt to fall, sometimes through inadvertence, sometimes through want of care, and the kind of action taken by the insurance committee, through its statutory subcommittee, in dealing with complaints.

CERTIFICATION.

An approved society complained of wrongful *certification under the following* circumstances. A young man was taken ill with rheumatic fever, seen and examined by his doctor and told to go to bed for three months. Regulations require in such a case that an official certificate should be given each week on any day between one Sunday and the next, but to be given on the day the doctor saw the patient or within twenty-four hours. The society and the boy's relations said the doctor did not call to see the boy or to give certificates which were fetched from the surgery. The doctor said he did call. A regional medical *officer* had been called to see the boy in consultation with the panel doctor who, in front of the regional officer, asked the mother and the hich I would refer is this: that Langdon-Down ggested the likeness between the imbecile mongoloids s I call them) and "members of the Mongolian race" ic) "might be due to admixture of Mongolian blood nongst Europeans." For this statement no justifica- on is known to me. Dr. Penrose's whole case against angdon-Down falls to the ground.

---

[1] See THE LANCET, 1931, ii., 87.

(2) Dr. Penrose then says that I have "endeavoured follow up this idea, supporting" my "contention y bringing forward many resemblances or 'homo- gies' which (I believe) are common to racial ongolians and this class of imbecile."

I am not quite sure what contention I am thought have endeavoured to follow up, but in my preface— nd elsewhere—I have made it clear (at the expense f repetition for which I have been severely blamed) at all I have consciously tried to do is to demonstrate ow, if my observations on the resemblances (which quite rightly call homologies) are correct, then, *ccepting certain Darwinian premises, we are logically rced to a polyphyletic theory of human origins* which ffords us a coherent and consistent explanation of mongolism." But, in this I am not *following*, I am pposing, Langdon-Down. He found, in his observa- ions, *proof* of the unity of the human race; I find, in he polyphyletic theory, an *explanation* of his observa- ions as confirmed and extended by me.

(3) Dr. Penrose goes on to say that "owing to andsteiner's discovery of the four blood groups" . . . a simple test can be applied to the theories of angdon-Down and Crookshank."

Before agreeing that a simple test can be applied o any theory of my own, I would much like to know n respect of which the test is to be applied. My propositions are set out categorically in Part IV., hapter II., of my book, and I cannot find among them one which is invalidated by anything shown by Dr. Penrose. To which of them is the "simple test" applicable? Moreover, I can find nothing in my remarks on the blood-grouping problems (on pages 276, 277, 278) that is inconsistent with any of Dr. Penrose's observations.

(4) Dr. Penrose gives, as his latest reference to Snyder's work, the paper in the *American Journal of Physical Anthropology* for 1926. This is a good paper, but research, to be up to date, should pay attention to Snyder's *book*, published in 1929, and referred to by me. Moreover, reference should be made to Prof. Haldane's lecture at the Royal Institution, on Feb. 20th, 1931, in which he says that the study of blood transfusion has proved that "all the peoples of the world" are divided into four blood groups, and that it now seems very probable *that humanity began in four different places*. In other words, Prof. Haldane finds that the study of blood-groups leads him to accept my proposition, that, *on the Darwinian premises, we are forced to a polyphyletic theory of human origins*. When I put this notion forward 20 years ago, I was laughed at, openly. To-day, I am happy to accept the work of the hæmatologists, so far as it goes, as confirming this proposition to which I have consistently adhered.

(5) Dr. Penrose says, however, that "an hypothesis was put forward by Crookshank that Mongolian imbeciles were related in some way to orang-utan monkeys." In saying this, Dr. Penrose is "arguing" much as Wilberforce did with Huxley, on a celebrated occasion. (According to Darwin and Huxley, both Dr. Penrose and myself are "related" to all sorts of monkeys, and even to amœbæ!) But Dr. Penrose writes as if I suggested "Mongolian imbeciles" to be a special breed of human or semi-human beings, isolated (like the Chillingham cattle) from their kin, and the offspring of really shocking affairs with "orang-utan monkeys." What I do suggest is that we get a good "explanation" of the phenomena of "mongolism" if we regard the *imbecile* mongoloids as expressing conflict between parental ancestral strains, the *non*-imbecile mongoloids being, not so much the result of conflict, as of harmony, between certain ancestral strains, united, or segregating out, in the parents ("The Mongol in our Midst," pp. 412, 440, et al). And, very happily for myself, this kind of conclusion has received confirmation from the work of Mjoen and others. This work shows us how in Scandinavia, where crossings still occur between "Nordics" and Lapps, sometimes one racial influence may be prepotent, sometimes a homogeneous blend may occur, sometimes some characters of each (race) may be present, and sometimes "each organ may be a kind of mosaic." More simply: when there is a double ancestral strain, sometimes a fairly high type with predominance of one influence, and sometimes degeneration and mental defect may occur. This is exactly what I have postulated in "explanation" of the phenomena of mongolism in Europe: if, that is, we accept the polyphyletic hypothesis.

(6) Now, what we really need to know is: how do the blood characters segregate out, in these circumstances? We want to know what are the blood group characters of the different types of Nordic-Lapponic crossings before we can say that anyone's results are "quite inconsistent with the theories of Langdon-Down and Crookshank." It is precisely because I wished to avoid any a priori conclusions, such as Dr. Penrose has made, that I wrote as carefully as I did concerning the blood grouping problem, on pp. 276–8 of my book.

(7) Finally, may I observe that Dr. Penrose is unfortunate in putting the statement that, in "European countries" A is much more common than B, in antithesis to the dictum that the incidence of B is high in Mongolian races. For Snyder finds a "Hunan" type, "with an exceptionally high frequency of A and a low frequency of B," in Korea, Japan, Southern China, and also *amongst Hungarians, Poles, Ukrainians, and Egyptians, suggesting the possibility of Mongolian relationships in the ancestry of these peoples*. In other words, the results given by Dr. Penrose suggest for the "Mongolian imbeciles" exactly what Snyder finds possible, and anthropologists admit, for many Central and Eastern Europeans!

(8) And there, I think, the hæmatological question must be left at present. I am not concerned to stress the importance of the blood groupings either way: too much still awaits examination. But I do think that those who are inclined to differ from me, on a priori grounds, should do me the compliment of finding out what it is I mean, or, at any rate, of accepting my word for it when I say what I mean.

Dr. Penrose's work does not invalidate or controvert a single statement that I have made, so far as I can see. If I am wrong, I will be happy to acknowledge my error, for, once more, I have tried to prove nothing but this: that, accepting certain observations, then, on the Darwinian hypothesis, we are forced to a polyphyletic theory of human origins, and have a consistent and coherent "explanation" of the occurrence of mongoloids among us.

But I wish some statistician would tell me what, according to Poisson's ratio, is the probability of error when, by means of a hundred or two blood examinations, a *petitio principii*, and some a priori

CORRESPONDENCE

ARTERIAL ATONY AND ARTERIO-SCLEROSIS.

To the Editor of THE LANCET.

SIR,—I cannot claim the authority to express an opinion upon the general argument embodied in Prof. Plesch's article in your current issue, but I cannot allow to pass unchallenged his assertions that athletes show marked calcification by the age of 35 or 40; that they are seldom capable of great physical effort when they attain middle life; and that most of them die before 50. In your annotation, "Another View of Arterio-sclerosis," you express the opinion that there may be many who will disagree with these assertions. I shall be surprised to find any who will agree with them. In a desire to reconcile contradictory opinions you suggest that Prof. Plesch may be referring to those who give their whole time to athletics and not to those who take part in sport merely as a recreation. I do not find it easy to picture precisely what is meant by the category of "whole-timers" unless it is an attempt to separate the amateur from the professional, a distinction which for several reasons is of no value.

Before dealing with Prof. Plesch's own assertions, I must refer to your statement that it is pretty generally agreed that exercise raises the blood pressure, in particular the systolic, considerably. This is perfectly true, but there is no support for your subsequent statement that the systolic pressure remains high for a considerable time after the exercise is finished and slowly returns to normal. On the contrary, the fall in blood pressure on the cessation of exercise is comparatively abrupt; and a return to the resting state (or a little lower) is to be expected in from one to four minutes. Possibly the proverbially low pressure of the athlete is what Prof. Plesch refers to as "the severe relaxation which follows all heavy bodily exertions," though it is strange to hear such a desirable condition invested with pathological significance.

In 1873 Morgan undertook a laborious investigation into the life-histories of all who had rowed in the Inter-University Boat Race between the years 1829–1869. In 1904 Meylan studied similarly the Harvard oarsmen who had rowed between 1852 and 1892. Their results were in close correspondence and showed a life expectation of nearly five years longer than that of the selected risks of insurance tables. They found, moreover, no evidence of impaired efficiency in regard to mental or physical activity and clearly they were dealing with a form of exertion which is universally accepted as the most exacting to which the human frame can be subjected.

The greatest long-distance runner in the world at the present day is well over 50 years of age. The holder of the 40 miles record established 49 years ago is an octogenarian who competed in races until he was 60, and made a practice until only a few years ago of running a mile on his birthday. Sexagenarians and septuagenarians could be enumerated literally in scores who, in their youth, were prominent performers in every branch of sport, and whose present condition for their age it would be impossible to surpass. As you submit in your annotation, arterio-sclerosis is an obscure condition and any thoughtful work on it is therefore welcome. But if the value of Prof. Plesch's paper depends upon the accuracy of his statements which refer to the influence of exercise, I do not think it will be a reliable contribution.

I am, Sir, yours faithfully,
ADOLPHE ABRAHAMS.

Brook-street, W., Feb. 22nd.

BLOOD GROUPING OF MONGOLIAN IMBECILES.

To the Editor of THE LANCET.

SIR,—Dr. L. S. Penrose has contributed to your issue of Feb. 20th some interesting information about blood grouping among Mongolian imbeciles. I cannot, however, forbear pointing out, in the interests of scientific truth, what I believe to be a fallacy in his argument.

Dr. Penrose appears to me to have assumed that some linkage exists between the Mendelian characters giving rise to the blood group reactions and those characters, whatever they may be, which are responsible for Mongolian appearance. No one, as far as I am aware, has ever supposed that such a linkage exists, the variation in the incidence of the A and B factors in different races being presumed to depend upon the racial ingredients from which the race, as we now know it, was originally derived. If the sporadic appearance of Mongol characters in imbeciles among white races is really due to the admixture of Mongol stock, this admixture of factors, usually latent, must have taken place in the distant past, and the racial characters must be as thoroughly "mixed in" as the blood group factors. Unless there is a linkage between Mongol characters and the B factor, there could now be no relation between them, and the "Mongol theory" would be neither supported nor refuted by the incidence of blood groups. As far as is known parents both belonging to Group O are as likely as any others to produce a Mongolian imbecile, although this imbecile could not conceivably contain the B factor.

Dr. Penrose's observations are of some intrinsic interest, but they appear to me to be in fact totally irrelevant to the theories of the origins of these imbeciles which he is considering.

I am, Sir, yours faithfully,
GEOFFREY KEYNES

Park-square West, N.W., Feb. 22nd, 1932.

To the Editor of THE LANCET.

SIR,—Dr. Penrose, in your last issue, makes som references to myself and my book ("The Mongol i our Midst," 1931) in terms which are perhaps necessar for sustention of the thesis that I am in the wrong but which do not seem to me, at first blush, to b related very closely to what I have said. May therefore try to express clearly what are my view as set out in the book in question?

But, may I first enter a protest against the continue use of the ugly expression "Mongolian imbeciles" This, if it means anything at all, means Mongolia persons who are imbecile. The use of it, in ou literature, for persons who are never Mongolian, an not always imbecile, gives offence: (1) to Japanes and Chinese ladies and gentlemen; and (2) to som English parents of the children who are neith Mongolian nor imbecile.

Surely it is much better to speak of the children an adults we have in mind, as *mongoloids*, indicatin marked mental defect, if need be, by the prefixatio of the word imbecile? We then have: (1) mongoloids and (2) imbecile mongoloids. (I can think of n objection to this terminology except that I hav suggested it; I have often considered the advisabilit in the general interest, of ascribing its invention someone else.)

(1) The first statement made by Dr. Penrose

ULCUS TROPICUM.

To the Editor of THE LANCET.

Sir,—I read with great interest Dr. Kerley's paper this subject in your issue of Jan. 30th (p. 235) and was impressed with the idea that he is seeking a cific treatment. Reference to a previous communi-ion of mine to THE LANCET (1930, ii., 1220) will ely satisfy him.

I live in a country (Transjordania) where the ulcus picum is quite common. Here it is called jericho jeresh ulcer. No matter how uncertain the iology may be, it is undisputed that the condition found only in hot (tropical and subtropical) countries. us it is reasonable to treat it with excessive cold. experience, as well as the experiences of stinguished dermatologists in Arabia, make me k upon solid carbon dioxide, which has a tempera-re of 79° C. below zero, as the specific of ulcus picum. Moreover, the beneficial effect of the cocytosis that follows application of the solid gas undeniable. By a special condensing apparatus, rbon dioxide gas, under pressure from iron cylinders, condensed within two minutes into solid snow. uterising the ulcer for a minute by the solid rbon dioxide thus obtained reduces it to a simple in ulcer that can be cured within two to three eeks, with a simple antiseptic dressing (e.g., ointments jellidol, rivanol, or protargol). And if the ulcer is seen early, it heals without leaving a scar. I do not need to cite cases to prove the specificity of the solid gas. What I related in my last communication is quite enough, and I have seen and cured tens of cases since. I like to ascertain that every case is examined microscopically, and is found positive for leishmania parasites.

I do not agree with Dr. Kerley that the condition is "very much more common in men than in women and children." In my experience it is more often seen in women. I have three patients under treatment now and they are all young girls. The reason for the difference is, I think, that women's dress leaves more parts exposed than men's. The general condition, also, is not much to be blamed, for all my patients are healthy and robust.

As to transmission, the mosquitoes are the primary factors in Arabia. Nevertheless, indirect infection by flies canot be ruled out.

I am, Sir, yours faithfully,

Feb. 11th, 1932. D. F. TUTUNJI.

SURGICAL SPIRIT.—In reply to Dr. R. Prosser White, Dr. L. P. Garrod writes to point out that the surgical spirit to which he was alluding is not "alcohol diluted 1 in 5 of water," but industrial alcohol (as generally used for surgical purposes) which contains 5 per cent. methyl alcohol, approximately 95 per cent. ethyl alcohol, and only a trace of water.

PUBLIC HEALTH SERVICES

MENTAL HOSPITAL REPORTS.

THE EAST SUSSEX COUNTY MENTAL HOSPITAL at HELLINGLY had 1279 patients in residence on an. 1st, 1931. The recovery-rate for the year was 37·6 per cent. and the death-rate 6·33 per cent. Of those discharged recovered 55 were previously ent out on trial, 25 of them with a money allowance. The general health of the patients was good apart from an attack of influenza, a small outbreak of measles, and a slight epidemic of diarrhœa. The commonest causes of death were pneumonia and hronic nephritis; there were only six deaths from uberculosis. The malarial treatment of general paralysis has been continued; two female patients ailed to develop malaria and of the remaining 16 cases two were discharged recovered and two were improved. One female patient benefited considerably from intrathecal injections of neosalvarsanised serum. Of a number of cases of dementia præcox treated with intramuscular sulphosin, 25 per cent. were discharged recovered. These two forms of therapy naturally throw considerable work on the laboratory, which has also found time to investigate acidosis, liver function, and renal functions in mental disease and to do a considerable amount of work for local authorities. Special efforts were made during the year to develop occupational therapy, and marked mental improvement has been *noted*. The visiting surgeon performed four major operations during the year, the ophthalmic surgeon saw 283 patients, and the dental surgeon visited weekly. Nine men had full parole, and 63 men and 132 women had parole within the estate. Three wards and four villas are open to the grounds. When the weather is favourable many of the patients have their meals out of doors. The visiting commissioners express regret that in so well-equipped a hospital there should be no X ray outfit. The shortage of nurses is slightly less acute. During the year seven attendants and 16 nurses obtained their R.M.P.A. certificate, bringing the total certificated and registered to 59 men and 61 women.

The WEST RIDING MENTAL HOSPITAL at STORTHES HALL housed 1856 patients at the end of 1930. The recovery-rate for the year was 22·92 per cent. and the death-rate 8·23 per cent. A number of patients were sent out on trial before discharge, 35 of them with money allowances. The general health was satisfactory; there were two cases of dysentery and a carrier was found. Only six patients were suffering from tuberculosis and there was no other epidemic disease. Twenty-two cases of general paralysis were treated with malaria and four recovered sufficiently for discharge; of the 50 patients treated during the last three years 7 have been discharged, 21 have improved, and 9 have died. Nine cases of dementia præcox were given intramuscular sulphosin but without any lasting improvement. The dental surgeon visited weekly and saw a large number of patients. An out-patient clinic is open on two afternoons a week at the hospital, but its success is unfortunately limited by its inaccessibility and a certain amount of prejudice. Ten men have full parole and 71 men and 13 women have parole within the grounds; four wards are "open door." The laboratory carried out a large number of routine investigations and all new cases admitted were tested for dysentery and typhoid. Of the nursing staff 48 men and 26 women are certificated or registered, four men and six women having obtained *their* R.M.P.A. certificate during last year.

The SOUTH YORKSHIRE MENTAL HOSPITAL at WADSLEY, near Sheffield, had 1954 patients resident on Dec. 31st, 1930. The recovery-rate for the year was 34·7 per cent. and the death-rate 9 per cent. Autopsies were held on 97·7 per cent. of the fatal cases. A severe form of diarrhœa, for which no cause could be found, attacked some female patients early in the year, but did not cause any deaths. There was one case of enteric fever, two of scarlet fever, two of dysentery, four of erysipelas, 10 of influenza, and 11 of tuberculosis. Leave of absence was granted to 132 men on 563 occasions and to 106 women on 307 occasions, full parole to 30 patients, reasoning, a "simple test" is applied to considerations *concerning descent through hundreds of thousands* of years and thousands of millions of Mongolians and "orang-utan monkeys." Cannot we look at things *sub specie æternitatis?* If we did, we should save ourselves much trouble, and all be as good friends as I am sure Dr. Penrose and I want to be.

I am, Sir, yours faithfully,

Wimpole-st, W., Feb. 19th, 1932. F. G. CROOKSHANK.

METEOROLOGICAL FACTORS AND HEALTH.

To the Editor of THE LANCET.

SIR,—In his interesting letter in your issue of Feb. 13th (p. 370) Fleet-Surg. W. E. Home claims that there is much more to learn about the influence of weather on health. Concerning the influence of various climates and different localities on sundry diseases we possess a wealth of literature, and much weighty opinion, but no facts worth serious consideration. It should be possible, with a little trouble, to ascertain how a sufficiently large number of cases fare in certain climates as compared with controls elsewhere, but I have seen no serious attempts to make these observations, and the individual instances which may be the source of the obiter dicta of great men are of little value. With State medicine expanded as it is to-day, it should be possible to carry out such work, and perhaps most easily in the domain of tuberculosis.—I am, Sir, yours faithfully,

Paignton, Feb. 18th, 1932. ERNEST WARD.

THE SPAHLINGER REMEDIES.

To the Editor of THE LANCET.

SIR,—The concluding sentence of your editorial in THE LANCET of Feb. 6th, dealing with the Spahlinger remedies, runs as follows: "Mr. Spahlinger may safely join the freemasonry of bacteriologists who share their knowledge for the benefit of medicine and mankind." I read this to mean that you invite Mr. Spahlinger to accept the canons which govern other bacteriologists, and by so doing enjoy the status and the security which such acceptance confers. I find, however, that your words have been construed by some to mean that, in your judgment, Mr. Spahlinger, by such revelation as he has made of the methods by which his tubercle vaccines are made, has already earned for himself this place alongside pioneers in the field of immuno-therapy.

I feel sure that such a construction of the words quoted above was not intended, nor does the general tenor of your remarks suggest it. It will not have escaped your attention that concerning his tubercle *serum*, and the formulæ relating to it, Mr. Spahlinger has said nothing at all. Yet it is this preparation upon which, in the main, he has for the past twenty years based his claim to *cure* tuberculosis. And it is upon this substance that his reputation with a certain section of the public, and with a few of the less critical members of the profession, rests.

Having watched, for several years, Mr. Spahlinger's fruitless efforts to get his remedies accepted and used by British doctors, whilst still insisting that these remedies shall remain of the nature of secret and proprietary *medicines, this present development* interests me greatly. Your readers at least, however, will not draw inferences from it that are not warranted by the facts. Many honest and generous offers have been made to help Mr. Spahlinger to finance his remedies. Five years ago, when his friends complained that his beneficent work was being starved for lack of funds, the *Daily Express* offered Mr. Spahlinger the handsome sum of £10,000 to further his researches on condition that he would give facilities to a small medical committee to examine his methods and to report upon them. The offer was not accepted.

Since *the acceptance into the freemasonry of* bacteriologists is, to adopt your own standard, limited to those who share their knowledge for the benefit of medicine and mankind, and since Mr. Spahlinger has not so shared his knowledge, his entry into that brotherhood must be deferred until he has fully complied with this requirement.

I am, Sir, yours faithfully,

THOMAS HORDER.

Harley-street, W., Feb. 15th, 1932.

*** Sir Thomas Horder's reading of our words is correct.—ED. L.

SIZE OF WOMEN'S FEET.

To the Editor of THE LANCET.

SIR,—In a demonstration of genuine period clothes dating from 1780 recently arranged in Bristol, it was found that none of the ladies taking part could put on the shoes corresponding to the earlier costumes, as they were much too small. Is the fact that women's feet were so much smaller 100 years ago well-recognised? If it is so, I suppose exercise and a healthier life have been responsible for the change.

I am, Sir, yours faithfully,

J. T. IRVING, M.D., Ph.D.

University of Bristol, Department of Physiology,
Feb. 20th, 1932.

THE EARLY TREATMENT OF RHEUMATIC DISEASE.

To the Editor of THE LANCET.

SIR,—Attention is being very properly called to the world-wide suffering caused by rheumatic disease and to the necessity, from a medical point of view, of getting to closer grips with the problems of cause and cure. In this connexion I am writing on behalf of the Committee of the Royal Mineral Water Hospital at Bath, a national institution nearly 200 years old, to point out to the medical profession the necessity of sending patients for treatment in the *early* stages of the disease. If that is done there is hope of a cure, but what so frequently happens is that the patien is sent to us as a last resort, partially or entirely incapacitated, when cure is out of the question, and a certain amount of alleviation is often all that can be done. If however doctors would bear in mind the great good that can be effected in the early stages of the disease and would advise their patients to apply for admission to this hospital as a *first and not* as a *last* resort, very great good would, without question, result (1) to the patients themselves, (2) to the knowledge and treatment of the disease from a medical point of view. I venture to ask you to insert this appeal in the hope that this most important matter may receive the attention it deserves.

I am, Sir, yours faithfully,

GODFREY LIPSCOMB,
President, Royal Mineral Water Hospital, Bath.

Feb. 18th, 1932.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

DANGEROUS DRUGS BILL.

The Earl of LUCAN (Captain of the Gentlemen-Arms), in moving the second reading of the ngerous Drugs Bill in the House of Lords on ednesday, Feb. 17th, said that its objects was to end the Dangerous Drugs Acts 1920–25 so far as s necessary to enable the Government to ratify e International Convention signed at Geneva in e summer of last year to limit the manufacture d to regulate the distribution of narcotic drugs. n extensive illicit traffic in such drugs as *morphine*, roin, and cocaine was being carried on in many rts of the world, and that traffic was facilitated by e fact that these drugs were being produced in antities largely in excess of the medical and scientific quirements of the world. The Opium Advisory ommittee of the League of Nations had advocated e limitation of the manufacture of these drugs and nsidered that the most effective step towards ppressing the illicit traffic would be to prohibit e production of quantities beyond those which were quired for medical and scientific purposes. Such mitation could only be brought about by inter-ational agreement.

The Bill was read a second time.

Clause 1 of the Bill is as follows :—

(1) The following shall be substituted for Subsection (1) f Section 8 of the Dangerous Drugs Act, 1920 (in this Act eferred to as "the principal Act"):—"(1) The drugs o which this part of this Act applies are—(*a*) medicinal pium; (*b*) any extract or tincture of Indian hemp; (*c*) morphine and its salts, and diacetylmorphine (commonly known as diamorphine or heroin) and the other esters of morphine and their respective salts; (*d*) cocaine (including synthetic cocaine) and ecgonine and their respective salts, and the esters of ecgonine and their respective salts; (*e*) any solution or dilution of morphine or cocaine or their salts in an inert substance whether liquid or solid, containing any proportion of morphine or cocaine, and any preparation, admixture, extract, or other substance (not being such a solution or dilution as *aforesaid*) containing not less than one-fifth *per cent.* of morphine or one-tenth per cent. of cocaine or of ecgonine; (*f*) any preparation, admixture, extract, or other substance containing any proportion of diacetylmorphine; (*g*) dihydrooxycodeinone, dihydrocodeinone, dihydromorphinone, acetyldihydrocodeinone, dihydromorphine, their esters and the salts of any of these substances and of their esters, *morphine-N-oxide (commonly* known as genomorphine), the morphine-N-oxide derivatives, and any other pentavalent nitrogen morphine derivatives; (*h*) thebaine and its salts, and (with the exception of methylmorphine, commonly known as codeine, and ethylmorphine, commonly known as dionin, and their respective salts) benzylmorphine and the other ethers of morphine and their respective salts; (*i*) any preparation, admixture, extract, or *other* substance containing any proportion of any of the substances mentioned in paragraph (*g*) or in paragraph (*h*) of this Subsection.

For the purpose of the foregoing provision the expression "ecgonine" means lævo-ecgonine, and includes any derivatives of ecgonine from which it may be recovered industrially, and the *percentage* in the case of morphine shall be calculated as in respect of anhydrous morphine.

(2) Subsection (2) of Section 8 of the principal Act (which empowers His Majesty to declare that Part III. of that Act shall apply to certain new derivatives) shall be amended by the insertion after the words "if improperly used" of the words "or is capable of being converted into a substance which is, or is likely to be productive, if improperly used."

Clause 2 declares that: (1) It shall not be lawful for any person in the United Kingdom to trade in or manufacture for the purpose of trade any products obtained from any of the phenanthrene alkaloids of opium or from the ecgonine alkaloids of the coca leaf, not being a product which was on the *thirteenth* day of July, nineteen hundred and thirty-one, being used for medical or scientific purposes: Provided that if His Majesty is at any time satisfied as respects any such product that it is of medical or scientific value, he may by Order in Council direct *that this* Subsection shall cease to apply to that product.

(2) If it is made to appear to His Majesty that a decision with respect to any such product as is mentioned in Subsection (1) of this Section has in pursuance of Article 11 of the Geneva Convention (No. 2) been communicated by the Secretary-General of the League of Nations to the parties to the said Convention, His Majesty, by Order in Council, may, as the case requires, either declare that the provisions of the said Part III. shall apply to that product in the same manner as they apply to the drugs mentioned in Subsection (1) of Section 8 of the principal Act as amended by this Act or apply the said Part III. to that product with such modifications as may be specified in the Order.

(3) His Majesty may by Order in Council apply Part III. of the principal Act, with such modifications as may be specified in the Order to any of the following drugs, that is to say, methylmorphine (commonly known as codeine) ethylmorphine (commonly known as dionin) and their respective salts.

It is provided in Clause 3 that Subsection (2) of Section 6 of the Dangerous Drugs and Poisons (Amendment) Act, 1923 (which defines the expression "corresponding law"), shall have effect as though the reference therein to the provisions of the Hague Convention included a reference to the provisions of the Geneva Convention (No. 1) and the Geneva Convention (No. 2).

Under Clause 4 an Order or Declaration made by His Majesty in Council under the Dangerous Drugs Act, 1920 to 1932, may be varied or revoked by a subsequent Order or Declaration made in the like manner and subject to the like provisions.

Clause 5 provides that the Act shall not extend to Northern Ireland except in so far as it amends the Dangerous Drugs Acts, 1920 to 1925, in relation to matters with respect to which the Parliament of Northern Ireland have not power to make laws. The Act is to come into operation on such date as His Majesty may by Order in Council appoint, and different dates may be appointed for different provisions of the Act and in relation to different countries. Lastly, Section 3 and Section 6 of the Dangerous Drugs Act, 1925, are repealed.

UNEMPLOYMENT.

"FAILURE TO INITIATE SUCCESSFUL MEASURES."

In the House of Commons on Wednesday, Feb. 17th, Mr. LAWSON moved on behalf of the Opposition :—

> "That this House, recognising the increasing gravity of unemployment and of the condition of the unemployed and their families, regrets the failure of the Government to initiate effective measures for the reconstruction of the economic life of the country and the short-sighted economy of expenditure on works of public utility, especially housing, and on schemes of allotments, whereby unemployment has been increased; and is of opinion that the administration of the means test is causing grave injustice and distress and that the machinery of the poor-law should not be used in connexion with applications for unemployment benefit."

He said that it must have come as a shock to the House and the country to learn that the unemployed had increased by 218,000 upon last month's figures. There were 7000 fewer employed than in October. Even the figure of 218,000 was not altogether accurate, for the Minister of Labour had told the House that during the past three months 130,000 people had lost their employment benefit or any transitional payment which they had previously received. To-day there were 2,750,000 persons unemployed; more than 2,000,000 wholly unemployed, 500,000 temporarily unemployed, and 100,000 casually employed.

"IF THERE WAS A WAR."

With the exception of a comparatively small margin these unemployed persons were men and women of the highest calibre and some of the finest craftsmen in the world to-day. Nothing was being done, and nothing was contemplated to meet the needs of the unemployed. If there was a war to-morrow masses of these people, particularly the youth, would become important people at once. But there was no war and they were scantily clad, half-fed, struggling to maintain their moral, and a menace generally to the vitality of the nation. The Government had taken 10 per cent. of the very meagre sum and restricted parole to 28 men. Four male and three female wards are open to the gardens and two male wards to the grounds generally. The staff of the Institution are assisted by a consulting physician, a consulting surgeon, and a consulting dentist. Out-patient clinics are held at the Sheffield Royal Infirmary and the Sheffield Royal Hospital, and over a thousand cases were seen during the year at each clinic. The treatment of general paralysis by induced malaria was continued, the total number of cases so treated now being 194. Twelve cases were discharged as recovered during the year. The laboratory, in addition to routine work, has carried out a systematic research for carriers of dysenteric organisms. A large number of patients were treated in the X ray and ultra-violet ray department and the dentist examined 542 patients. During the year 14 attendants and 14 nurses obtained their R.M.P.A. certificate, and one nurse obtained the G.N.C. certificate.

At the STIRLING DISTRICT MENTAL HOSPITAL there were 1015 patients on May 15th, 1931, and 24 voluntary patients in addition. The question of overcrowding is receiving the anxious consideration of the new joint committee. The hospital contains a number of mental defectives and senile patients who could with benefit to themselves and to the institution be accommodated elsewhere. The recovery-rate for the year was 40·3 per cent. and the death-rate 10·8 per cent.; post-mortem examinations were carried out whenever permission was given. During the year 14 patients were sent out on trial to their friends. The general health was good, and there was no epidemic disease. The electro-therapeutic department treated 227 patients with good results, and the X ray apparatus was used for diagnosis in 16 cases. The dentist visited weekly and saw 236 patients, many of them with marked oral sepsis. The patients have derived much benefit from their work in the occupational therapy department, and a ready sale has been found for the articles made. The able-bodied male patients work on the farm and garden, and the year was so successful that a balance of £2409 was recorded. The laundry is now entirely worked by electricity and has been cheerfully decorated. During the year eight nurses and nine attendants obtained the R.M.P.A. certificate, which is now held by 40 per cent. of the entire nursing staff.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED FEB. 13TH, 1932.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 70 (last week 57); scarlet fever, 1422; diphtheria, 991; enteric fever, 31; pneumonia, 1968; puerperal fever, 39; puerperal pyrexia, 97; cerebro-spinal fever, 54; acute poliomyelitis, 4; acute polio-encephalitis, 2; encephalitis lethargica, 14; continued fever, 1; dysentery, 16; ophthalmia neonatorum, 99. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Feb. 16th–17th was as follows: Small-pox, 118 under treatment, 4 under observation (last week 105 and 4 respectively); scarlet fever, 1175; diphtheria, 1526; enteric fever, 9; measles, 1127; whooping-cough, 340; puerperal fever, 16 (plus 12 babies); encephalitis lethargica, 220; poliomyelitis, 4; "other diseases," 233. At St. Margaret's Hospital there were 19 babies (plus 10 mothers) with ophthalmia neonatorum.

Deaths.—In 117 great towns, including London, there was no death from small-pox or enteric fever, 49 (13) from measles, 6 (2) from scarlet fever, 50 (3) from whooping-cough, 29 (10) from diphtheria, 44 (9) from diarrhœa and enteritis under two years, and 279 (56) from *influenza. The figures in parentheses* are those for London itself.

The reported deaths from influenza are still falling slowly, but the total deaths for the year so far amount to 1990 against 1579 for the corresponding period of 1931. Of the great [illegible] from [illegible] Manchester, and Leicester each with 8. Manchester reported 7 deaths from measles, Portsmouth and Liverpoo each 5. Whooping-cough accounted for 9 deaths at Liverpool, 5 each at Manchester and Birmingham.

The number of stillbirths notified during the weel was 279 (corresponding to a rate of 46 per 1000 births) *including 50 in London.*

THE SERVICES

COMMISSIONS IN THE ROYAL ARMY MEDICAL CORPS.

THE War Office announces that the successf candidates for Commissions in the Royal Arm Medical Corps during January last were as follows D. P. F. Mulvany, Charing Cross; C. S. Gross, Guy' Hospital; J. B. Macfarlane, University of Aberdeen P. J. Richards, St. Bartholomew's Hospital; R. I MacRae, University of Aberdeen; R. St. J. Lybur Trinity College and Dublin; J. V. Quinn, Roy *College of Physicians and Surgeons,* Ireland.

Vacancies still exist, and particulars can be obtaine either by letter, or personally from the Assista Director-General, Army Medical Services, The W Office, London, S.W.1.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments have been notified: Su Lt. Comdrs. A. L. McDonnell to *Canterbury*, and A. de Joyce to *President*, for course. Surg. Lt. J. J. Keevil *Alecto.*

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Lts. E. A. H. Hindhaugh and J. F. Heg to be Surg. Lts.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. H. E. Priestley is placed on the half-pay list account of ill-health.

Maj. (temp. Lt.-Col.) A. E. B. Jones to be Lt.-Col.

Maj. A. Hendry to be temp. Lt.-Col.

The undermentioned Lts. (on prob.) are confirmed their rank: J. T. Robinson, W. A. Robinson, F. K. B A. Macdonald, W. R. M. *Drew*, J. B. George, W. B Brennan, and B. Blewitt.

The undermentioned to be Lts. (on prob.): J. B. Ma lane, and is secd. under the provisions of Art. 213, R Warrant for Pay and Promotion, 1931, W. R. Pa (since decd.), and P. J. Richards.

TERRITORIAL ARMY.

Col. R. E. Bickerton to be Hon. Col. 56th (1st Lond.) Div

Lt.-Col. F. T. Rees to be Bt. Col.

Lt.-Col. & Bt. Col. L. A. Harwood, from R.A.M.C., T.A. to be Col., and to be A.D.M.S., 56th (1st Lond.) Div. T.A. vice Col. R. E. Bickerton.

Maj. T. C. Bowie, R.A.M.C., to be Divl. Adjt., 52nd (Lowland) Div., vice Capt. C. A. Hutchinson, R.A.M.C. who vacates the appt. on completion of tenure.

Maj. G. G. B. Holroyde, R.A.M.C., to be Divl. Adjt. 48th (S. Midland) *Div.*, vice *Maj.* W. Y. Eccott, R.A.M.C. who vacates the appointment on completion of tenure.

Maj. J. L. Hamilton to be Lt.-Col. and to command the 167th (City of London) Fd. Amb.

B. A. Pain to be Lt.

ROYAL AIR FORCE.

Flight Lt. H. C. Sutcliffe Pimblett is granted a permanen commission in this rank.

INDIAN MEDICAL SERVICE.

R. I. Reid and F. C. Jackson to be Lts. (on prob.).

The undermentioned appts. have been made in India:— D.D.M.S.: Maj.-Gen. J. F. Martin. A.D's.M.S.: Col B. H. V. Dunbar, W. W. Browne, J. C. Kennedy, an Lt.-Col. N. E. Dunkerton. R.A.M.C. D.A.D's.M.S.: Maj E. E. Holden, R.A.M.C., and W. Bruce, R.A.M.C. A.D.H. Maj. T. B. Nicholls, R.A.M.C. *A.D's.H. & P.*: Lt.-Col. A. M Fraser, R.A.M.C., and Maj. F. R. Coppinger, R.A.M.C D.A.D's.P.: Majs. F. R. Coppinger, R.A.M.C., and D. T. M Large, R.A.M.C.

rch 1st.—Major ELLIOT (Financial Secretary to the asury) replied: As hydrocarbon oils are goods chargeable h an existing duty of customs, they will not be affected the proposals in the Import Duties Bill, which are what resume my hon. friend has in mind.

Health of Acrobatic Performers.

Mr. DENVILLE asked the Minister of Health whether his urns showed any appreciable premature mortality or rtness of life in excess of normality among those who had en trained as children for acrobatic and similar work and d earned their livelihood in this branch of entertainment.—E. HILTON YOUNG replied: I regret that no statistics e available in my Department on this subject.

THURSDAY, FEB. 18TH.

Dermatitis and Compensation to Workmen.

Sir VIVIAN HENDERSON asked the Home Secretary ether there had been an increase or a decrease in the umber of cases of dermatitis in the last three years for ich compensation had been paid; and whether any eps were taken by his department to encourage the wearing gloves or mittens in appropriate cases.—Sir HERBERT MUEL replied: The Workmen's Compensation Statistics t 1928, 1929, and 1930 (which is the last year for which gures are available) show an increase in the number of ses. There were 1170 cases in 1928, 1405 in 1929, and 99 in 1930. Various steps have been taken by the Department to enforce or encourage the wearing of gloves as a ecaution against dermatitis. For example, gloves are quired for persons employed in various processes under the hemical Works Regulations of 1922, and the Chromium lating Regulations of 1931, and under the Welfare Order 1918 for use of bichromate potassium or sodium in dyeing, e Hollow-ware and Galvanising Welfare Order of 1921, nd the Tanning Welfare Order of 1930. Further, a general aflet providing information as to the causes of dermatitis nd recommending precautions, including the use of gloves, as been prepared and widely distributed among occupiers f works likely to be affected, and, with a view to securing he coöperation of the workers, a form of cautionary notice hich can be exhibited in the workrooms has been issued nd put on sale through the Stationery Office. Reference also made to the value of gloves in certain special emoranda dealing with the prevention of dermatitis in articular processes. Finally, I may draw attention to the ollection of different kinds of gloves suitable for the purpose hich is on exhibition in the special dermatitis section at he Home Office Industrial Museum in Horseferry-road, Westminster.

Medical Research Committee and Spahlinger Formula.

Mr. HAMMERSLEY asked the Minister of Health when he xpected to receive the observations of the Medical Research ouncil and other competent research bodies on the statement by Mr. Spahlinger containing a formula for the treatment of tuberculosis.—Sir E. HILTON YOUNG replied: I am unable at present to say when it is likely that these observations will be received.

Sterilisation of Mentally Deficients.

Dr. MORRIS-JONES asked the Minister of Health whether he had now considered the setting up of a committee of experts to investigate and report on the question of the sterilisation of the mentally deficient; and when he would be in a position to announce the names of the members of the committee.—Sir E. HILTON YOUNG replied: I have not yet determined the precise form of inquiry which is likely to yield the best results.

Improvement of Unhealthy Areas.

Mr. JOHN asked the Minister of Health if he would state from the passing of the Housing Act, 1930, the number of schemes for the improvement of unhealthy areas submitted to the Ministry and the number confirmed; how many schemes had been undertaken by local authorities and the number completed; the total amount paid on account by the State towards slum clearance; and the ultimate State liability in respect of schemes approved, in continuation of the information given on Feb. 12th, 1931.—Sir E. HILTON YOUNG replied: Up to Jan. 31st last I had received resolutions declaring 377 areas in England and Wales to be clearance areas, and 10 areas to be improvements areas under the Housing Acts, 1930. These resolutions do not require confirmation by me. Complete returns have not yet been received, but at least 308 houses had been demolished in the areas in question by Dec. 31st last. The amount paid on account by the State towards slum clearance during the year 1931 was £83,672, and the ultimate annual State liability is roughly estimated at £280,000.

Results of 1931 Census.

Mr. BROCKLEBANK asked the Minister of Health when he would be able to publish the results of the Census, 1931.—Sir E. HILTON YOUNG replied: It is anticipated that the series of Census Reports will begin to be published about the middle of this year; but it cannot at present be stated when the publication of all reports will be completed.

Appointments of Medical Referees and Assessors.

Mr. THOMAS WILLIAMS asked the Home Secretary if he would take steps to prevent any medical referee or medical assessor being appointed under the Workmen's Compensation Act where such medical referee or medical assessor was acting from time to time in his professional capacity on behalf of the employers, indemnity companies, or workmen's trade union.—Sir HERBERT SAMUEL replied: It is a condition of the appointment of a medical referee that he shall hold no regular employment either on the employers' or on the workers' side, and the medical referees are enjoined that in their private practice they should, as far as possible, avoid cases which may come before them in their official capacity. It has not been considered necessary or practicable to impose more stringent restrictions, but if the hon. Member has some individual case in mind, and will send me particulars, I shall be glad to make any necessary inquiry.

Carbon Monoxide Gas in Coal-mines.

Mr. TINKER asked the Home Secretary if he was aware that, owing to the increased use of explosives and other causes in coal-mines, carbonic oxide gas was generated which caused incapacity and, in some cases, death; and if he would consider placing this among the scheduled diseases under the Workmen's Compensation Act.—Sir HERBERT SAMUEL replied: This question is not a new one and has been examined more than once. In particular, a proposal to schedule poisoning by this gas was considered and rejected by the Industrial Diseases Committee of 1907, on evidence that the effects of such poisoning are invariably sudden and therefore in the nature of accidents, and already covered as such by the Act. The question whether all cases are so covered has however been recently referred for further examination to the Industrial Diseases Committee, now sitting under the chairmanship of Sir Humphry Rolleston, and if the hon. Member is aware of any cases showing the need for an extension of the schedule, I would suggest that he should send full particulrs to the Secretary of the Committee at the Home Office.

London Refuse.

Mr. MCENTEE asked the Minister of Health if it was proposed to take any action on the Report of the Departmental Committee on London Cleansing, issued in May, 1930; and whether any regulations were to be issued prohibiting the dumping of crude refuse in dumps adjacent to villages or occupied houses in the Home counties.—Sir E. HILTON YOUNG replied: The Metropolitan Authorities have been pressed to discontinue the insanitary tipping of refuse, and active measures have been taken by some of them. The main recommendations of the Departmental Committee would require legislation, of which I see no prospect this session. But the Town and Country Planning Bill now before Parliament contains proposals for empowering local authorities to control the deposit of refuse by provisions in planning schemes.

Salaries of Local Government Officers.

Mr. HICKS asked the Minister of Health whether the temporary voluntary abatements of wages and salaries which local government officers and servants had been subjected to as a result of the national economy measures were to be taken into account for the basis of pension; and, if so, whether he would consider making amendments to the Superannuation Acts that affected local government officers and servants, so that their pension rights should not be reduced as a consequence of these temporary abatements.—Sir E. HILTON YOUNG replied: I have asked the several associations of local authorities for their views as to the desirability of legislation for this purpose. The further consideration of the matter must await the receipt of their replies.

Grading of Milk.

Lord SCONE asked the Minister of Health whether he would consider the advisability of reclassifying the various grades of milk produced in this country, and also the present position, in which the consumer was led to believe that Grade A milk was the highest class produced, whereas it was in reality only of third-class quality.—Sir E. HILTON YOUNG replied: I will consider the matter in consultation with my right hon. friend the Minister of Agriculture and Fisheries. But any reclassification of graded milks on the lines suggested by my noble friend would require legislation, provided for the unemployed. The Chancellor of the Exchequer spoke the other night about the cost of living being artificially low. If the right hon. gentleman could try for a week the standard of living of some of these people he would know that the cost of living in proportion to the money which they received was very high. He asked the Government whether it was not time that they considered the restoration of the money which had been cut off unemployment benefit. The Government had better be careful what they did in the way of relieving the taxation of the comfortably placed classes in view of the state of mind of the people of this country at the present time. The Minister of Labour stated in January that on Dec. 21st there were 742.222 men and 97,000 women with applications for transitional benefit. The claims of 683,442 men and 78,000 women were authorised for payment, while the needs of 59,000 men and nearly 19,000 women were not held by the local authorities to justify payment. That was roughly the starting of the operation of the means test. When everything was said and done the fact remained that the Government had put nearly 1,000,000 unemployed persons into the same position as the paupers of this country. He urged the Government to take this motion seriously. The living of many people depended upon it. There were children lacking shoes to-day as a result of the present policy.

Mr. TINKER seconded the motion.

GOVERNMENT REPLY TO CRITICISM.

Sir HENRY BETTERTON (Minister of Labour) said that during the first seven or eight months of last year—in fact until the Labour Government left office—the unemployment figures increased month by month until they reached their peak at that time. Had it not been for the very heavily increased taxation which the present Government were compelled to lay on the shoulders of the people of this country last October there was very little question but that the situation would be much better than it was to-day. When the Labour Government was in office two years the results of their efforts to reconstruct the economic life of the country was that the country was brought to the verge of bankruptcy. During that period unemployment increased by 136 per cent., or by 1,500,000. If that was their idea of reconstructing the economic life of the country, it was indeed a lesson and a warning. The present Government was asked to continue the vicious circle of increased national expenditure and increased rates. If that were done it would increase unemployment. Much of the criticism which had been levelled against the needs test in the House and in the country was due to a very imperfect appreciation of the fact that transitional payments were not insurance benefit, but State maintenance paid to those who had exhausted their insurance rights. Was the Labour Party in favour of State relief being given, without any insurance qualification and without any consideration as to the means of the applicants?

THE POOR-LAW STIGMA.

In the administration of this matter by the Public Assistance Committees the Government had taken every step in their power to ensure that what was called the stigma of the poor-law should not affect the applicants at all. Some lack of uniformity was inevitable where there were different bodies administering these cases in different areas. On the other hand, it was only right that there should be some lack of uniformity, because it might be that in some districts rents and the cost of living were higher. He had done his best, however, to see that the means test was not worked harshly or unfairly. As a result of representations which had been made to him, and as a result of the advice and efforts of the inspectors of the Ministry of Health, the discrepancies had now been largely removed. There were still some discrepancies arising from a difference in poor-law conditions and practice, but he understood that the Minister of Health was going to summon a conference of public assistance committees from the difficult areas and to ask them to consider jointly how variations in practice, for which no justification could be proved, could be removed. As to the question of disability pensions, he had satisfied himself that in the interests of the disabled men themselves justice could best be done by individual and sympathetic treatment of cases on their merits. The Public Assistance Committees had the necessary discretion to take into account the extra needs of a disabled man.

SIGNS OF RETURNING CONFIDENCE.

He believed that there were signs at this moment of returning confidence in the country. If they regarded the position as it was last August, and the prospects to-day, it was clear that the country was gradually, painfully, and very slowly surmounting some of these difficulties which last summer seemed absolutely overwhelming. With a balanced budget and with determination on the part of all sections of the community to face realities, the failure to do which in the past had been so largely the cause of our troubles, the country could look forward to the future with a good deal more confidence than seemed possible last year. (Cheers.)

SPECIAL COMMISSION TO BE CALLED.

After further debate,

Sir E. HILTON YOUNG (Minister of Health) said that in addition to the conference of Public Assistance Committees (which had been referred to by the Minister of Labour) he proposed, in order that there might be an even wider coöperation between different areas, to call a conference of what he might call a special commission or departmental committee of the most experienced inspectors of the Ministry of Health, who should attend the area conferences and spread the light of information and coördination from one part of the country to the other. In that way they would be able to get rid, by the natural process of administration, of those variations in practice which were unnecessary. The Government would watch for any opportunity of promoting works which would provide employment subject to two conditions: first, that the works would be definitely remunerative; and secondly, that they could not just as well be undertaken by private enterprise without Government assistance. They desired to turn away once and for all from the policy, which was followed like a will-'o-the-wisp by the Labour Government, to a policy of economy which they believed was essential to the welfare of the country.

The motion was rejected by 415 votes to 39.

DANGEROUS DRUGS BILL.

The Dangerous Drugs Bill passed through Committee in the House of Lords on Tuesday, Feb. 23rd, with one small drafting amendment.

HOUSE OF COMMONS.

WEDNESDAY, FEB. 17TH.

Hospitals and Motor Accident Cases.

Dr. HILLMAN asked the Minister of Transport if he was aware that, from a recent inquiry by the Yorkshire Voluntary Hospitals Committee relative to the number of third-party motor accidents treated in 36 hospitals in Yorkshire during the first six months working of the Road Traffic Act, 1030 it appeared that the total cost incurred by the hospita for treating these cases amounted to £4500, of which sum only £123 was recovered from accident insurance companies; and whether he would amend the Road Traffic Act accordingly.—Mr. PYBUS replied: While I sympathise with the difficulties of the hospitals, I am afraid I cannot see my way to introduce further legislation.

Duty on Imported Petrol.

Sir VIVIAN HENDERSON asked the Chancellor of the Exchequer whether it was the intention of the Government that the existing duty on imported petrol and similar oils should still apply to such imports from the Empire after ch 1st.—Major ELLIOT (Financial Secretary to the asury) replied: As hydrocarbon oils are goods chargeable a an existing duty of customs, they will not be affected the proposals in the Import Duties Bill, which are what esume my hon. friend has in mind.

Health of Acrobatic Performers.

Mr. DENVILLE asked the Minister of Health whether his ers showed any appreciable premature mortality or rtness of life in excess of normality among those who had n trained as children for acrobatic and similar work and learned their livelihood in this branch of entertainment.—E. HILTON YOUNG replied: I regret that no statistics available in my Department on this subject.

THURSDAY, FEB. 18TH.

Dermatitis and Compensation to Workmen.

Sir VIVIAN HENDERSON asked the Home Secretary ether there had been an increase or a decrease in the mber of cases of dermatitis in the last three years for ich compensation had been paid; and whether any ps were taken by his department to encourage the wearing gloves or mittens in appropriate cases.—Sir HERBERT MUEL replied: The Workmen's Compensation Statistics 1928, 1929, and 1930 (which is the last year for which ures are available) show an increase in the number of es. There were 1170 cases in 1928, 1405 in 1929, and 59 in 1930. Various steps have been taken by the Department to enforce or encourage the wearing of gloves as a ecaution against dermatitis. For example, gloves are quired for persons employed in various processes under the emical Works Regulations of 1922, and the Chromium ating Regulations of 1931, and under the Welfare Order 1918 for use of bichromate potassium or sodium in dyeing, e Hollow-ware and Galvanising Welfare Order of 1921, nd the Tanning Welfare Order of 1930. Further, a general aflet providing information as to the causes of dermatitis nd recommending precautions, including the use of gloves, as been prepared and widely distributed among occupiers f works likely to be affected, and, with a view to securing e coöperation of the workers, a form of cautionary notice hich can be exhibited in the workrooms has been issued nd put on sale through the Stationery Office. Reference s also made to the value of gloves in certain special emoranda dealing with the prevention of dermatitis in articular processes. Finally, I may draw attention to the ollection of different kinds of gloves suitable for the purpose hich is on exhibition in the special dermatitis section at he Home Office Industrial Museum in Horseferry-road, Westminster.

Medical Research Committee and Spahlinger Formula.

Mr. HAMMERSLEY asked the Minister of Health when he xpected to receive the observations of the Medical Research ouncil and other competent research bodies on the statement by Mr. Spahlinger containing a formula for the treatment of tuberculosis.—Sir E. HILTON YOUNG replied: I am unable at present to say when it is likely that these observations will be received.

Sterilisation of Mentally Deficients.

Dr. MORRIS-JONES asked the Minister of Health whether he had now considered the setting up of a committee of experts to investigate and report on the question of the sterilisation of the mentally deficient: and when he would be in a position to announce the names of the members of the committee.—Sir E. HILTON YOUNG replied: I have not yet determined the precise form of inquiry which is likely to yield the best results.

Improvement of Unhealthy Areas.

Mr. JOHN asked the Minister of Health if he would state from the passing of the Housing Act, 1930, the number of schemes for the improvement of unhealthy areas submitted to the Ministry and the number confirmed: how many schemes had been undertaken by local authorities and the number completed: the total amount paid on account by the State towards slum clearance: and the ultimate State liability in respect of schemes approved, in continuation of the information given on Feb. 12th, 1931.—Sir E. HILTON YOUNG replied: Up to Jan. 31st last I had received resolutions declaring 377 areas in England and Wales to be clearance areas, and 10 areas to be improvements areas under the Housing Acts, 1930. These resolutions do not require confirmation by me. Complete returns have not yet been received, but at least 308 houses had been demolished in the areas in question by Dec. 31st last. The amount paid on account by the State towards slum clearance during the year 1931 was £83,672, and the ultimate annual State liability is roughly estimated at £280,000.

Results of 1931 Census.

Mr. BROCKLEBANK asked the Minister of Health when he would be able to publish the results of the Census, 1931.—Sir E. HILTON YOUNG replied: It is anticipated that the series of Census Reports will begin to be published about the middle of this year; but it cannot at present be stated when the publication of all reports will be completed.

Appointments of Medical Referees and Assessors.

Mr. THOMAS WILLIAMS asked the Home Secretary if he would take steps to prevent any medical referee or medical assessor being appointed under the Workmen's Compensation Act where such medical referee or medical assessor was acting from time to time in his professional capacity on behalf of the employers, indemnity companies, or workmen's trade union.—Sir HERBERT SAMUEL replied: It is a condition of the appointment of a medical referee that he shall hold no regular employment either on the employers' or on the workers' side, and the medical referees are enjoined that in their private practice they should, as far as possible, avoid cases which may come before them in their official capacity. It has not been considered necessary or practicable to impose more stringent restrictions, but if the hon. Member has some individual case in mind, and will send me particulars, I shall be glad to make any necessary inquiry.

Carbon Monoxide Gas in Coal-mines.

Mr. TINKER asked the Home Secretary if he was aware that, owing to the increased use of explosives and other causes in coal-mines, carbonic oxide gas was generated which caused incapacity and, in some cases, death; and if he would consider placing this among the scheduled diseases under the Workmen's Compensation Act.—Sir HERBERT SAMUEL replied: This question is not a new one and has been examined more than once. In particular, a proposal to schedule poisoning by this gas was considered and rejected by the Industrial Diseases Committee of 1907, on evidence that the effects of such poisoning are invariably sudden and therefore in the nature of accidents, and already covered as such by the Act. The question whether all cases are so covered has however been recently referred for further examination to the Industrial Diseases Committee, now sitting under the chairmanship of Sir Humphry Rolleston, and if the hon. Member is aware of any cases showing the need for an extension of the schedule, I would suggest that he should send full particulrs to the Secretary of the Committee at the Home Office.

London Refuse.

Mr. MCENTEE asked the Minister of Health if it was proposed to take any action on the Report of the Departmental Committee on London Cleansing, issued in May, 1930: and whether any regulations were to be issued prohibiting the dumping of crude refuse in dumps adjacent to villages or occupied houses in the Home counties.—Sir E. HILTON YOUNG replied: The Metropolitan Authorities have been pressed to discontinue the insanitary tipping of refuse, and active measures have been taken by some of them. The main recommendations of the Departmental Committee would require legislation, of which I see no prospect this session. But the Town and Country Planning Bill now before Parliament contains proposals for empowering local authorities to control the deposit of refuse by provisions in planning schemes.

Salaries of Local Government Officers.

Mr. HICKS asked the Minister of Health whether the temporary voluntary abatements of wages and salaries which local government officers and servants had been subjected to as a result of the national economy measures were to be taken into account for the basis of pension; and, if so, whether he would consider making amendments to the Superannuation Acts that affected local government officers and servants, so that their pension rights should not be reduced as a consequence of these temporary abatements.—Sir E. HILTON YOUNG replied: I have asked the several associations of local authorities for their views as to the desirability of legislation for this purpose. The further consideration of the matter must await the receipt of their replies.

Grading of Milk.

Lord SCONE asked the Minister of Health whether he would consider the advisability of reclassifying the various grades of milk produced in this country, and also the present position, in which the consumer was led to believe that Grade A milk was the highest class produced, whereas it was in reality only of third-class quality.—Sir E. HILTON YOUNG replied: I will consider the matter in consultation with my right hon. friend the Minister of Agriculture and Fisheries. But any reclassification of graded milks on the lines suggested by my noble friend would require legislation.

and I regret that at present I cannot contemplate the introduction of legislation on this subject.

Milk Prosecutions.

Mr. GLOSSOP asked the Minister of Health the number of prosecutions that have taken place in England during 1929, 1930, and 1931, in connexion with milk deficient in fat, together with the number of convictions obtained.

Brigadier-General CLIFTON BROWN asked the Minister of Health how many prosecutions for too low a percentage of butter fat under the Milk Adulteration Order came before the courts in 1931; and in how many of these cases were convictions obtained.—Sir E. HILTON YOUNG replied: I regret that I am unable to give all the information asked for, but in 1931 there were 98 prosecutions for the sale of adulterated milk in London, and convictions were obtained in 51 cases, two being still outstanding. The total number of samples of milk reported as adulterated in England and Wales is roughly 15 times the number so reported in London.

Brigadier-General CLIFTON BROWN asked the Minister of Health how many samples of fresh liquid milk were taken during the last three months by the port sanitary authorities of London, Harwich, and Newhaven, respectively; and whether any of these liquid milk imports were rejected for not being up to standard requirements in cleanliness and butter fat.—Sir E. HILTON YOUNG replied: The answer to the first part of the question is 8, 49, and 13 respectively. Three samples taken at Harwich and seven taken at Newhaven failed to comply with the bacterial standard laid down, and the importation of milk from the sources of supply of these samples has been discontinued. Ninety-three samples taken at the ports in question were examined by the Government chemist, and none was reported as deficient in butter fat.

Death Sentence on Young Persons.

Mr. GOLDIE asked the Home Secretary of State for the Home Department the number of occasions on which since the year 1922 sentence of death had been pronounced upon persons between the ages of 16 and 21; and in how many cases capital punishment had been executed in the said period upon such persons.—Sir HERBERT SAMUEL replied: During the ten years from 1922 to 1931 inclusive the figures were 18 and 4. I would add that the executions took place in the years 1922, 1923, 1925, and 1926, and that the ages were between 18¼ years and 20½ years.

Slum Clearance in Lancashire.

Mr. HAMILTON KERR asked the Minister of Health how many slum clearance schemes had been approved in Lancashire, and in which towns, since the passing of the Housing Act of 1930.—Sir E. HILTON YOUNG replied: Seventy-two clearance areas have been declared in Lancashire. The following is a list of the towns concerned. *County Borough Councils:* Bolton, Bootle, Liverpool, Manchester, Preston, Rochdale, Salford, and Wigan. *Non-County Borough Councils:* Ashton-under-Lyne, Eccles, Leigh, and Rawtenstall. *Urban District Councils:* Atherton, Dalton-in-Furness, Farnworth, Leyland, Newton-in-Makerfield, Orrell, Prestwich, Swinton and Pendlebury, and Whitefield.

Rural Housing.

Mr. PARKINSON asked the Minister of Health how many houses had been approved under the Housing (Rural Authorities) Act, 1931.—Sir E. HILTON YOUNG replied: The Committee appointed under the Act have informed 110 authorities that they are prepared to entertain applications to the extent of 1733 houses for the agricultural population.

TUESDAY, FEB. 23RD.

Radium Research.

Sir ERNEST GRAHAM-LITTLE asked the Minister of Health if he would consider the advisability of promoting the formation of a committee of inquiry to take evidence and to report as to the best methods of forwarding radium research and advising as to the most useful application of the sums of public money subscribed for that purpose and at present in the custody of the National Radium Trust.—Sir E. HILTON YOUNG replied: My hon. friend will be aware that, as has already been stated in the House on several occasions, the Radium Trust and the Radium Commission are not appointed by the Minister of Health, but are constituted by Royal Charter. It is the duty of the Radium Commission under Article 7 of the Charter to make arrangements for the proper custody, equitable distribution and full use of the radium which may from time to time be the property of the Trust, with the object of promoting the treatment of the sick throughout Great Britain and the advancement of knowledge of the best methods of rendering such treatment and of securing due economy in the use of radium for the purposes of such treatment; [illegible] to them for the use of the ra[illegible] arrange the supply on loan [illegible] the radium or any preparations of it so as to enable proposals approved by them to be carried out. I have, therefore, in the first instance referred my hon. friend's suggestion to the Radium Commission for their consideration, and I will inform him of their views in due course.

Post-vaccinal Encephalitis.

Mr. GROVES asked the Minister of Health how many cases of, and deaths from, post-vaccinal encephalitis or other disease of the central nervous system following vaccination had been brought to the notice of his department since the adoption of the new vaccination regulations on Oct. 1st 1929.—Mr. ERNEST BROWN (Parliamentary Secretary to the Ministry of Health) replied: Since Oct. 1st, 1929 38 cases of suspected disease of the central nervous system following vaccination, including suspected cases of post-vaccinal encephalitis, have come to the notice of my department. Inquiries showed that in at least five of these cases the suspicion could not be verified. In 18 causes vaccination had been followed within a short period by the occurrence of a disease of the central nervous system without there being any reason to associate this disease with the antecedent vaccination. Of these 13 were fatal. There remain 15 cases in which the occurrence of post-vaccinal encephalitis was definitely established, and of these eight proved fatal.

Miners' Hours Convention.

Mr. MANDER asked the Secretary for Mines the present position with reference to the international convention for miners' hours.—Mr. ISAAC FOOT replied: His Majesty's Government is favourably disposed towards the Convention. The detailed application of some of its provisions to the coal-mines of this country presents certain problems which are under consideration. As soon as these points have been disposed of, the Government will be prepared to ratify the Convention provided that the other six countries will do so at the same time.

Gas Detectors in Coal-pits.

Mr. HANNON asked the Secretary for Mines when he proposed to undertake the experiment of the introduction of gas detectors into certain coal-pits; and if he would explain the process by which the proposed practical tests would be carried out.—Mr. ISAAC FOOT replied: I have asked the interests directly concerned—including the Mining Association and the Miners' Federation—to coöperate in organising and watching thorough pit trials on a working scale with an automatic firedamp detector. It is my hope that the scheme—which will require to be worked out carefully—will be settled by common consent, and discussions to that end will be conducted as speedily as possible.

DONATIONS AND BEQUESTS.—Among other bequests the late Mr. Henry Atkinson, of Birkenhead, left £500 each to the Liverpool Royal Infirmary, the Liverpool Southern Hospital, the Liverpool Northern Hospital, and the Liverpool Children's Hospital; £200 to the Liverpool Eye and Ear Infirmary and the School for the Blind, £1000 to Ulverston Cottage Hospital, and 4 per cent. of the residue, with a maximum of £400, to the Liverpool Cancer Fund.

NEWCASTLE INFIRMARY: REJECTION OF CONTRIBUTORY SCHEME.—By 24 votes to 16 the house committee of Royal Victoria Infirmary, Newcastle-on-Tyne, rejected a proposal for the establishment of a contributory scheme, the chairman remarking that up to the present the Infirmary had been able to meet fairly satisfactorily all the demands made upon it. The suggestion to put into force some scheme of compulsory contribution was warmly espoused by Sir Robert Bolam in a recent address to county hospital representatives, in which he pointed out that the workers in Northumbria were contributing directly about £130,000 towards the £300,000 spent annually on keeping up voluntary hospitals. Adding thereto the employers' contribution, which amounted to about 20 per cent. of that of the workpeople, there remained double that total to be raised by donations, subscriptions, and investments. He pleaded for equality of effort among those who ought to support hospitals, adding his own belief that the money to carry on and extend the services would not be forthcoming without compulsion. A contributory scheme would have the further advantage of facilitating interchange of patients among the different hospitals in the area.

OBITUARY

WILLIAM FREDERICK HASLAM, M.B., Ch.B. Birm., F.R.C.S. Eng.

ONSULTING SURGEON, BIRMINGHAM GENERAL HOSPITAL.

'E regret to announce the death on Feb. 18th at residence in Vicarage-road, Edgbaston, of Mr. iam Frederick Haslam, sometime professor of ery in the University of Birmingham, after a onged illness, at the age of 74.

rof. Haslam received his medical education at Thomas's Hospital Medical School, having viously been articled, in the old-fashioned manner, member of the surgical staff of the Royal Berkshire spital, Reading. He spent over two years at Reading, l as a student at St. Thomas's Hospital he soon tinguished himself by his aptitude for anatomy. became assistant demonstrator in the subject l gained the Cheselden medal in anatomy and gery. He qualified as M.R.C.S. in 1878, held the ual resident appointments at the hospital, and was de a prosector in anatomy at the Royal College Surgeons of England. In 1881 he obtained the llowship of the College, and in the following year was cted assistant surgeon at the Birmingham General spital.

For the rest of his professional life Prof. Haslam orked in Birmingham. At Queen's College, rmingham, he was appointed medical tutor in 1883, id in the following year demonstrator of anatomy, hich post he held till 1892. He became full surgeon the General Hospital in 1891, and held this position ll the end of the war, his term of office being prolonged despite the age regulation for retirement. His ork as a surgeon, always characterised by a proound knowledge of anatomy, was of a very sound rder, and his clinical teaching was practical and uch appreciated by the students. On the ormation of the University of Birmingham in 900 he was appointed lecturer in applied anatomy, hen lecturer in general surgery to the dental chool, and finally, in 1908, joint professor of urgery from 1913 to 1919. On retiring from the hair he accepted the post of dean of the medical aculty in the University, and held this office, together ith the lectureship in applied anatomy, until 1928. hroughout this long period of service he discharged he duties with a zeal and interest which were reflected the high opinion formed of him by his colleagues, ho on his retirement from active work made a resentation to him as "a token of affection and ratitude for valuable services to the medical and ental schools and the University during the period f 46 years—1882 to 1928." *The University Medical* ociety instituted at his retirement a Haslam Oration n memory of his long association with the medical chool.

Haslam was much esteemed outside his own niversity as an examiner, acting in this capacity or two periods, in anatomy, for the primary ellowship of the Royal College of Surgeons of ngland, while he examined in surgery at different imes for the Universities of London, Liverpool, Leeds, and Bristol. At the College of Surgeons he was a member of Council from 1908 to 1924, serving as vice-president for two years, and as chairman of the court of examiners. In 1911 he was Lettsomian ecturer at the Medical Society of London, and delivered a series of lectures upon operations for tone in the male bladder,* which were reported in our columns; but he was a quite infrequent contributor to medical literature.

Sir Gilbert Barling adds the following simple and sympathetic words upon his life-long colleague: "Haslam and I were associated for nearly fifty years in hospital and in university work. I do not think he had an enemy in the world; he was above all things loyal, kindly, and highly conscientious in his work. In the later period of his life, when he might well have left to one of his junior colleagues the urgency calls of night emergencies at hospital, he always insisted on attending to them himself, this not because he wished to deprive his juniors of experience but from a very high sense of duty. He was not so much marked as a dexterous operator—operation work was, I always thought, a considerable strain upon him—but he rose to the occasion when difficulties presented themselves, and he never did anything wild or rash. But his powers of diagnosis were excellent, and his opinion was often invited by his colleagues in difficult cases. As a teacher he was very methodical and effective, whether in the wards or in the anatomy rooms; in the latter he had the gift, not too common in these days, of adapting the parts of anatomy to their applications in surgery—a gift which made him very popular with students. For some time after he had retired from his hospital surgeoncy he continued his anatomical teaching greatly to the advantage of the school of medicine. As an examiner he was admirable both in the earlier and in the later subjects; his experience in this work was quite exceptional, and he really liked it—which can probably be said of few surgeons. His fairness, his desire to do justice to what the student knew, rather than to find out his weakest points, gave the victims under examination a sense of confidence and of fair treatment which brought out the best in them.

"For several years he was dean of the faculty of medicine in the University. The duties are not easy to carry out owing to the rather conflicting interests of the two main teaching hospitals, which are again somewhat aggravated by the dispersion of the teaching centres—*two hospitals apart from each* other and from the University buildings. Haslam's tact, his fairness and his integrity, secured a degree of harmony such as could have been attained by hardly anyone else; and his guidance of students, as well as of colleagues gathered around him a degree of affection of which any man might be proud.

"About four years ago he had a disabling illness which rendered him a complete invalid and at times gave him much distress. He bore his troubles with such dignity and courage as might be expected from him, having regard to the tenour of his life. May he rest in peace."

WALTER GEORGE SMITH, M.D. Dub., F.R.C.P. Irel.

Dr. Walter Smith, who died suddenly at his house in Merrion-square, Dublin, on Feb. 23rd, was formerly president of the Royal College of Physicians of Ireland, and also of the Royal Academy of Medicine in Ireland. He was King's professor of materia medica and pharmacy in the School of Physic, Trinity College, Dublin, from 1881 to 1920, and in this post he succeeded his father, Aquilla Smith, who had held the chair from 1864.

Walter Smith was educated at Trinity College, Dublin, taking an honours degree in experimental science in 1867. He graduated as M.B. in the same year, and as M.D. in 1870. In 1868 he was elected a Fellow of the King and Queen's (subsequently Royal) College of Physicians in Ireland, of which, after filling various other offices, he became president in 1892. To the end of his life he took great interest in the affairs of the College, and until a few months ago rarely missed one of its meetings. He was "Father of the College" since the death of John Mallet Purser a few years ago. His chair of materia medica carried with it the duty of physician to Sir Patrick Dun's Hospital. He was also for several years physician-in-ordinary to the Lord Lieutenant, Earl Cadogan.

Smith's professional life had two main interests—dermatology and chemistry. In both he attained distinction. His occasional communications dealing with dermatology were authoritative, and although he never limited his practice as a physician to that specialty, he always took a great interest in it. In early life he considered entering on an academic career as a teacher of chemistry, but circumstances did not favour this scheme. He was, however, an ardent student of chemistry all his life, and on his gradual withdrawal from practice in recent years chemistry became his main intellectual interest. Rarely did a session pass without his bringing a paper dealing with recent developments in chemistry before the Royal Academy of Medicine or the private medical club he was in the habit of attending. "His experience as a physician and his knowledge of chemistry made him an ideal teacher of materia medica," writes a colleague. "He succeeded in being both scientific and practical. His scientific outlook, his mind sharp to a degree of scepticism, freed that complicated subject from the entanglements of tradition and superstition which tended, more 40 years ago than to-day, to render it a pathless wild. As a clinical teacher his effect was stimulating rather than informative. He brought everything to the test of science and common sense; he hated sham of every kind, in himself as well as in others; authority appealed as little to him as did mere novelty; pomposity and pretence angered him. Withal he had a simple and genuine humanity which endeared him to his students."

Births, Marriages, and Deaths

BIRTHS.

HARE.—On Feb. 16th, at a nursing home, the wife of Major John Hare, O.B.E., R.A.M.C., of Radnor-place, W., of a daughter.

SMALLEY.—On Feb. 19th, at "Stockcroft," Malthouse-lane, Kenilworth, the wife of Leonard Smalley, M.B., M.R.C.S., of a son.

DEATHS.

BLACKMAN.—On Feb. 12th, at Poplar House, Portsmouth, Josiah Geo[illegible] ux., for nearly 50 years in medical [illegible]

FORDYCE.—On [illegible] ng home in Cambridge, Boston Elphinstone Fordyce, M.B., of Stirling-road, Bournemouth, aged 73 years.

HASLAM.—On Feb. 18th, at his residence, Vicarage-road, Edgbaston, Prof. William Frederick Haslam, M.B., B.Ch., F.R.C.S., aged 74.

KINDNESS.—On Feb. 16th, at his residence, Castle Hill-avenue, Folkestone, John Kindness, M.R.C.S., L.R.C.P., aged 49 years.

PRICHARD.—On Feb. 18th, at Almeley, Bodenham-road, Hereford, from pneumonia, following typhoid, John Augustin Prichard, M.R.C.S., L.R.C.P.

SMITH.—On Feb. 16th, at Merrion-square, Dublin, Walter George Smith, M.D., F.R.C.P.I., ex-President Royal College of Physicians, Ireland, in his 88th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

MEDICAL NEWS

University of London.

At a meeting of the Senate on Feb. 17th the William Julius Mickle Fellowship for 1932 was awarded to Mr. Philip Eggleton, D.Sc., for his research on the labile compounds of phosphorus in muscle.

The title of Fellow of University College, London, was conferred on Mr. Harold John Channon, D.Sc., Johnston Professor of Biochemistry in the University of Liverpool; Dr. Henry Albert Harris, professor of clinical anatomy at University College and University College Hospital Medical School; and Mr. Herbert Tilley, late surgeon to the ear, nose, and throat department of University College Hospital. The title of Honorary Fellow of the University College, London, was conferred on Sir Edward Hilton Young, Minister of Health.

University of Edinburgh.

The Cameron prize for 1932 has been awarded to Dr. Edward Mellanby, F.R.S., professor of pharmacology in the University of Sheffield. The prize, whose value is about £200, is awarded annually for additions made to practical therapeutics during the previous five years.

University of Manchester.

Dr. J. F. Wilkinson, director of the laboratory of clinical investigations, has been appointed lecturer in systematic medicine, and Dr. Allan Taylor demonstrator in anatomy. Dr. J. M. Yoffey has resigned his appointment as assistant lecturer in anatomy on his appointment as lecturer in anatomy in the University College of South Wales and Monmouth.

Pharmaceutical Society of Great Britain.

At a meeting to be held at 17, Bloomsbury-square, London, W.C., at 8.30 P.M., on March 8th, Mr. Frank Wokes will give an address on the Importance of Ergot in Pharmacy.

Gresham College.

Four lectures on Great English Doctors and their Message will be given by Sir George Newman at Gresham College, Basinghall-street, London, E.C., at 6 P.M., on March 1st, 2nd, 3rd, and 4th.

Dr. Alfred Cox Testimonial Fund.

A communication has been sent out by the committee of this fund to the chairmen, secretaries of the divisions, and representatives of the British Medical Association, asking that as many names as possible should be added to the list of subscribers, so as to make that list a complete one of the Association.

Society of Radiographers.

The eleventh annual dinner of the Society was held at Pritchard's Restaurant on Friday last, Feb. 19th, Mr. Cyrus L. Winch, the president of the Society, being in the chair. The main toast of the evening, the "Prosperity of the Society," was proposed by Dr. A. E. Barclay, president of the British Institute of Radiology (B.I.R.), who referred in obstetric terms to the dates of origin of the Rontgen Society and the British Association for the Advancement of Radiology and Physiotherapy and their amalgamation as the B.I.R. in 1927, in which year the Society of Radiographers, founded seven yea[illegible] became also affiliated to the B.I.R., though [illegible]ntity. Dr. Barclay congratulated th[illegible]aphers on an increasing membership and the intention to maintain a high standard of entrance. Mr. Winch replied setting out well the inter-relations which should exist between radiographers and radiologists, alluding to the former as the head and the latter as the limbs of a joint pursuit of beneficent knowledge. The toast of the "Guests and Visitors" was proposed by Mr. C. W. Furby and replied to from different angles by Dr. H. A. Harris, professor of clinical anatomy in University College, London, and Dr. Cecil Teall, president of the [illegible]raphic Society. Dr. Teall pointed out the [illegible] to be derived from the development o[illegible]ursuit of their joint science in the large provincial centres, while Professor Harris was both instructive [illegible] the necessity for the insistence upon [illegible]ards of entrance. With regard to [illegible] Harris pointed out that their utility was [illegible] enhanced if they were well conducted, paying here a great tribute to the work at the English Conjoint Board of Sir Frederick Hallett, whose organisation of examinations he considered to constitute a model, rendering the task of the examiner less harassing, while assuring for the examinee "a square deal." Mr. C. E. A. Bedwell, house governor of King's College Hospital, also replied, and the evening closed with an entertainment consisting of an amusing dialogue by Messrs. Clapham and Dwyer.

National Temperance Hospital.

e "London" has now been re-named the "National" perance Hospital.

ruction for D.P.M.

om the London County Council we have received a bus of lectures and practical courses of instruction to iven at the Maudsley Hospital from the beginning of h onwards, intended primarily for candidates for a ma in psychological medicine. Particulars of these other facilities for instruction may be had from the tor of the Central Pathological Laboratory, Maudsley ital, Denmark-hill, London, S.E. 5.

essional Nursing, Midwifery, and Public Health nference.

the first day of this conference, which is to be held e New Horticultural Hall, Westminster, S.W., from 29th to March 4th, addresses on the following among subjects will be given: THE LANCET Commission rsing, by Mr. Bradford Hill, D.Sc. (2.30 P.M.); Bookings t-patients, by Miss G. M. Wortley: Hospital Organisa- by Mr. Godfrey Hamilton.

Physics Building at Leeds.

t week Sir William Bragg opened the new physics ing of Leeds University, which has been provided at of £60,000. Sir William, who was formerly Cavendish sor at Leeds, recalled that in the old building researches een made which had opened the way to discovery e world over. There Stroud had produced the range- the first measurements of X ray spectra were made , and the first observations were recorded which mined the structure of crystals.

L.C.C. and the Nursing Commission's Report.

last week's meeting of the London County Council, ral Cuthbert Hunter asked the chairman of the central health committee whether, in view of the report of LANCET Commission on Nursing, she would consider, llaboration with the education committee, the desir- of training girls for the nursing profession from the f 16, and so enable girls leaving central schools to their training without any break in their education? arrie Lambert stated, in reply, that the final report Commission would be before the central public health ittee on Feb. 25th, and the committee would, she pated, ask the medical officer of health to report to fully on the subject of the Commission's recommenda- With regard to the particular point raised by Admiral r, as to taking girls at the age of 16 for training for tioner nurses, this question, she said, had for some been, and still was, under consideration by the com- .

sh Social Hygiene Council.

eeting of this Council was held on Feb. 16th in London, Sir Basil Blackett, the president, in the chair, to receive ort from the executive. The report evidenced the sion of the Council's work and its increased coöperation allied societies. The voluntary and other economies time were mentioned, the chairman remarking that ss of the block grant was not wholly a disadvantage; illors, now approached personally, had had their st practically awakened. A book, "Preparation for age," has been compiled and will soon be on sale, and to girls in preparation for marriage is to be given bureau to be opened with the approval of the Council. ouncil's two new films were cordially approved. Sir m Beveridge addressed the meeting on the aim of ritish Broadcasting Corporation in issuing its "Family n."

fields Dinner.

annual dinner of past and present students of the London Ophthalmic Hospital was held at the Langham , London, on Feb. 11th, when Sir William Lister led, and among those present were Sir Harold Fawcus, Admiral St. G. S. Bond, Sir Peter Chalmers Mitchell, rnold Lawson, K.B.E., Mr. Theodore Luling (chairman e hospital), Dr. Gordon Holmes, and Mr. Treacher s. The "Hospital and Medical School," proposed by hairman, was responded to by Mr. Luling and Mr. es Goulden, dean of the school. In submitting his al report, the dean said there were 161 students attend- e hospital, of whom 77 were new. Moorfields students nted for 31 of the 38 successful candidates for the almic diploma of the Conjoint Board. For the Oxford ma 5 of the 7 successful candidates came from Moor- . During the year also 3 students had obtained the S. Edin. The enlargement of the out-patient depart- and medical school proposed two years ago were, id, now likely to be put in hand, giving even better ties for teaching.

Devonshire Hospital, Buxton.

Sir Humphry Rolleston, Regius professor of physic in the University of Cambridge, has been elected president for 1932–33 of the Devonshire Hospital for Rheumatic Diseases, Buxton.

Maternity Block at West Middlesex Hospital.

On Wednesday last week the Queen opened the new maternity block and electrical treatment department at the West Middlesex county hospital, Isleworth, which was opened by the Duchess of Teck, her mother, in 1897. It is a two-floored building with maternity wards, nursery, infants' sun-rooms and bathing-rooms, labour-room, and glazed verandahs. The antenatal department has a separate entrance, and the theatre is on the ground floor.

Appointments

CRAMERI, P. V., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon, under the Factory and Workshop Acts, for New Southgate, Middlesex.

Medical Referees under the Workmen's Compensation Act: BROCKMAN, R. ST. L., M.Ch. Camb., F.R.C.S. Eng. (Doncaster and East Retford); GALLOWAY, T. McL., F.R.C.S. Edin. (Clackmannan County).

Vacancies

For further information refer to the advertisement columns.

Aberdeen Royal Mental Hospital.—Jun. Asst. Phys. £300.

All Saints' Hospital, 91, Finchley-road, N.W.—H.S. At rate of £150.

Antrim Mental Hospital, N. Ireland.—Res. Med. Supt. £800.

Ashton-under-Lyne District Infirmary.—H.S. At rate of £150

Birmingham, Maternity and Child Welfare Dept.—Res. M.O. £250.

Blackburn, Calderstones (Certified Institution for Mental Defectives) Whalley.—Asst. M.O. £500.

Bootle Ge —Hon. Orthopædic Surgeon.

Bradford At rate of £135.

Brighton sst. School M.O. and Asst. to th

Bristol E Surgeon.

British M Med. Secy. £800.

Cambridge, Addenbrooke's Hospital.—Three H.S.'s to Special Depts. Each at rate of £130.

Cancer At rate of £100.

Cardiff, *al Memorial Associa tior*

Cardiff r. £200. Also H.P. At rate of £50.

Charing Cross Hospital, Strand, W.C.—Surg. Reg. £150. Also Obstet. Reg. £100.

Croydon General Hospital.—Hon. Asst. P.

Durham County Hospital.—Two H.S.'s. Each £150.

East Ham Memorial Hospital, Shrewsbury-road, E.—H.P. and H.S. and Cas. O. At rate of £150 and £120 respectively.

Exeter, Royal Devon and Exeter Hospital.—Cas. O. and H.S. to Spec. Depts. At rate of £150.

Great Barrow, Nr. Chester, East Lancs., Tuberculosis Colony.—Asst. M.O. At rate of £275.

Greenwich, Dreadnought Hospital.—H.P. and H.S. Each at rate of £110.

Halifax, St. Luke's Hospital.—Sen. Res. M.O. £350.

Harrogate Infirmary.—Jun. H.S. £140.

Hertford County Hospital.—H.S. At rate of £200.

Hospital for Sick Children, Great Ormond-street, W.C.—Cas. O. £400.

Hospital for Tropical Diseases, Endsleigh-gardens, W.C.—H.P. At rate of £150.

Hove, Lady Chichester Hospital.—Jun. H.P. At rate of £50.

Ipswich, East Suffolk and Ipswich Hospital.—H.S. and H.P. Each £120.

King's College Hospital, Denmark-hill, S.E.—Jun. Surg. to Ear, Nose, and Throat Dept.

Leicester Royal Infirmary.—H.S. and H.P.'s. Each at rate of £125.

M.O. £100.

spital.—Second Asst. M.O. £425.

an-street, W.—Surg. Reg. £100.

-road, W.—Surg. Reg. £100.

Park Place, Cheetham Hill-road.

Manchester, Royal Children's Hospital, Pendlebury.—Res. M.O. At rate of £125.

Manchester, Royal Children's Hospital, Gartside-street.—Two Asst. M.O.'s. Each at rate of £150.

Manchester Royal Infirmary.—Med. Reg. to Out-patients. At rate of £150.

Miller General Hospital, Greenwich-road, S.E.—Res. Surg. O. and Reg. £250. Also H.P. £150. Also Anæsthetist. 52 gns.

National Hospital for Diseases of the Heart, Westmoreland-street, Marylebone, W.—Res. M.O. Also Out-patient O. At rate of £150 and £125 respectively.

ospital for Sick Children.—H.P. Also s. Each at rate of £100.

Hospital, Edmonton.—Jun. Res. Asst.

Nottingham City Mental Hospital.—Second Asst. M.O. £100.

Oxford, Pembroke College.—Theodore Williams Medical Scholarship. £100.
Portsmouth Royal Hospital.—H.S. At rate of £130.
Prince of Wales's General Hospital, Tottenham, N.—Sen. and Jun. H.P.'s and H.S.'s. At rate of £120 and £90 respectively.
Princess Louise Kensington Hospital for Children, St. Quentin-avenue, N. Kensington, W.—H.P. At rate of £75.
Queen's Hospital for Children, Hackney-road, E.—H.P. and Cas. O. Each at rate of £100
Richmond, Sur [illegible] Jun. H.S. At rate of £100.
Rotherham Hos [illegible]
Royal London [illegible] *City-road, E.C.*—Two Out-patient Of [illegible]
Royal Nationa [illegible] *234, Gt. Portland-street, W.* H.S. At [illegible] 2 H.S.'s for Country Branch, Brockley H [illegible] of £150.
Royal Northern [illegible] 's. M.O. £200.
St. John's Hospi [illegible] *49, Leicester-square, W.C.*—Out- [illegible] Each £50.
St. Leonards-on-Sea, Buchanan Hospital.—Jun. H.S. At rate of £125.
St. Peter's Hospital for Stone &c., Henrietta-street, Covent Garden, W.C.—H.S. At rate of £75.
St. Thomas's Hospital.—Ophth. Reg. and Refractionist.
Salford Royal Hospital.—Res. H.S.'s to Special Depts. Each at rate of £125.
Sheffield, Jessop Hospital for Women.—H.S. At rate of £100.
South Metropolitan Gas Co., Old Kent-road, S.E.—Chief M.O. £1000.
Southend-on-Sea New General Hospital.—Hon. Surgeons and Physicians, &c. Also Res. M.O. £400.
Southern Rhodesia Medical Service.—Asst. and Relieving Govt M.O. £500.
Swanley, Kent, Hospital Convalescent Home, Parkwood.—Res. M.O. At rate of £200.
Walsall General Hospital.—H.P. and Res. Pathologist and H.S. Each at rate of £150.
West Riding of Yorkshire County Council.—School Med. Inspectors. £500.
Wigan, Royal Albert Edward Infirmary.—Three H.S.'s Each at rate of £150.
Wolverhampton Royal Infirmary.—Res. Asst. S. £250. Also H.S. to Ear, Nose, and Throat Dept. At rate of £100.

The Home Secretary gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act (1925) for the Sheriffdom of Lanark, and that it is proposed to appoint a *surgeon* to fill the vacancy. Applications from *Surgeons* should be addressed to the Private Secretary, Scottish Office, Whitehall, London, S.W.1, and should reach him not later than March 15th, 1932.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, [illegible]
TUESDAY, March 1st.—8 P.M., [illegible] Followed by Mr. J. P. Hosford and Mr. E. P. Brockman. SURGERY. Members of this section are *specially invited to attend.*
WEDNESDAY.—5 P.M., HISTORY OF MEDICINE. *Paper:* Dr. [illegible] The History of the Introduct [illegible] to Medicine. Speakers: Sir [illegible] Sir [illegible] Dr. T. Izod Bennett, a [illegible] SURGERY. Short Pap [illegible] D. W. C. Northfield: [illegible] about the Elbow. M [illegible] of Head of the Radi [illegible] thelioma of Lymph N [illegible] Exposure of t [illegible]
THURSDAY.—8 P.M., [illegible] Paper: Dr. [illegible] Belgian Congo [illegible] of African Natives as Medical Assistants.
FRIDAY.—10.30 A.M., OTOLOGY. (Cases at 9.30 A.M.) Papers and slides: Dr. A. de Kleyn and Dr. A. Gray: A Case of Bilateral Acoustic Tumour. Dr. A. Gray: *Pathological Changes in the Auditory Nerve.* Cases and specimens. 5 P.M., LARYNGOLOGY. (Cases at 4 P.M.) Discussion: The Treatment of Suppurating Maxillary Sinusitis. Openers: Mr. W. M. Mollison Mr. A. J. Wright. Paper: Dr. Douglas Guthrie: The Operative Closure of *Oromaxillary Fistula.* Cases and *specimens.* 8.30 P.M., ANÆSTHETICS. Paper: Dr. C. W. Morris: Anæsthesia for Major Throat Operations. LARYNGOLOGY. Members of this Section are specially invited to attend.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Feb. 29th.—9 P.M., Mr. F. A. Williamson-Noble: *The Reactions of the Eye to General Disease.* (First Lettsomian lecture.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.
TUESDAY, March 1st.—5 P.M., Dr. L. J. Witts: Pathology *and Treatment of Anæmia.* (First Goulstonian lecture.)
THURSDAY.—5 P.M. (Second Goulstonian lecture.)

GUY'S HOSPITAL, London Bridge, S.E.
MONDAY, Feb. 29th.—5 P.M., Dr. A. F. Hurst: Use of X Rays in Physical Diagnosis.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.
TUESDAY, March 1st.—3.15 P.M., Dr. E. G. B. Calvert: *Practical Points: Cases of Diabetes, Nephritis, and Goitre.*

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, University-street, W.C.
TUESDAY, March 1st.—5.15 P.M., Dr. Dorothy Russell: Intracranial Tumours.

CHARING CROSS HOSPITAL MEDICAL SCHOOL.
SUNDAY, Feb. 28th.—10.45 A.M., Mr. H. E. Batten: Flat Foot. 11.45 A.M., Dr. A. A. W. Petrie: Diagnosis and Treatment of General Paralysis of the Insane.

NATIONAL HOSPITAL, Queen-square, W.C.
MONDAY, Feb. 29th.—2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Kinnier Wilson: Epilepsy.
TUESDAY, March 1st.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Carmichael: Myasthenia.
WEDNESDAY.—2 P.M., Dr. Martin: Out-patient Clinic.
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Gordon Holmes: Symptoms of Cerebellar Disease.
FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Carmichael: Myopathy.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark-hill, S.E.
THURSDAY, March 3rd.—9 P.M., Mr. V. E. Negus: Diseases of the Œsophagus.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James' Hospital, Ouseley-road, Balham.
WEDNESDAY, March 2nd.—4 P.M., Dr. E. Young: Treatment of Gastric and Duodenal Ulcer by Duodenal Feeding.

THURSDAY, March 3rd.—Mr. E. D. McCrea: Pneumothorax Demonstration.

ST. MARY'S HOSPITALS, Manchester.
FRIDAY, March 4th.—4.15 P.M. (at the Whitworth-street West Hospital), Dr. Dougal and Dr. Brentnall: Antenatal Demonstrations.

LOCK HOSPITAL, Glasgow.
WEDNESDAY, March 2nd.—4.15 P.M., Dr. David Watson: *Venereal Diseases (Female).*

NOTES, COMMENTS, AND ABSTRACTS

ECONOMIES IN PRESCRIBING.

> "There can be no doubt that we doctors unintentionally very often involve our patients in xpenses which represent an unnecessary export f our money abroad, and are, from the medical point of view, quite superfluous."

ıs quotation, taken from a paper by the regian pharmacologist, Prof. E. Poulsson, in *skrift for den Norske Laegeforening* for Feb. 1st, mptomatic of the world-wide agitation against rts and in favour of reduction of expenditure. in the territory of each Great Power, the money by the manufacturing chemist is, so to speak, in the family. In the smaller States, on the hand, the popular drugs with protected names to a large extent to be imported, chiefly from ıany. According to the fashionable economic ine, medical men in these countries have a le incentive to economise by prescribing drugs r their chemical instead of their trade names. Prof. Poulsson points out, only a few decades the new pharmacological impulses usually came university laboratories unconcerned with the nercial side of the matter. At the present time place of these laboratories is in this direction taken more and more by the large chemical ries possessed of far greater material resources often equipped with first-rate facilities for rimental research in laboratories staffed by alists who coöperate on a sound footing with itals and similar institutions. After years of rch and clinical tests a new drug, if it proves factory, is put on the market at as high a price ommercial considerations allow, and the process anufacture is patented for a certain number of s, 18 for example. If the drug is really valuable, profit from such a monopoly with a time limit ell earned. The situation is somewhat different the protected name. the monopoly of which no time limit. A drug whose simple chemical position has long been known, and whose pretion is perfectly easy, can be given a plausibly estive new name and foisted on the public ıeans of intensive propaganda.

ten the difference between the prices of one and same drug sold under a protected name and its ical name is enormous. In the 1930 edition the "Arzneiverordnungsbuch der Deutschen ıeimittelkonmission," a commission on which German Society for Internal Medicine, the nan Pharmacological Society, and other important es are represented, a table is published comparing prices for a given weight when sold under this or name. A few examples may be given here.

ıtity nmes.	Protected name.	M.	Chemical name.	M.
0	Antipyrine	0·70		0·50
0	Atophan	4·40		1·20
1	Diuretin	0·20		0·05
1	Hetol	0·50	Sod. Cinnamas	0·10
1	Protargol	0·35	Argent. Proteinic	0·10
1	Urotropine	0·40	Hexamethylene-tetramine	0·05
1	Veronal	0·45	Acid. Diethyl-barbituric	0·10

Price in marks when sold under—

en as much as 3 g. a day have to be taken the ent may have to discontinue a valuable remedy ply because his medical adviser has not troubled rescribe the drug at the cheaper rate.

hemical titles are often difficult to memorise, and his connexion it may be recalled that in 1905, he Conférence Internationale pour l'Unification de Formule des Médicaments Héroïques, held in ssels, the suggestion was made that an international pharmacological body should be created, of whose duties should be to give short names to gs whose scientific names are too long. These rt names must, of course, be in their turn proed lest a commercial concern should corner them. s idea has been favourably received in certain quarters; as an example we may mention the name barbitone given to diethyl-barbituric acid in the British Pharmacopœia.

Prof. Poulsson quotes Nottebaum as having calculated that in Germany the sickness insurance funds are taxed to the tune of 50 million marks a year for superfluous drug bills. Quoting Trendelenburg, he refers to the host of trade synonyms for one and the same substance; for adrenalin there are 29 such synonyms, for the posterior lobe of the pituitary body there are 34, for the thyroid there are 31, and for digitalis a modest 41. In Norway a pharmacological commission is at present studying this problem, and it is significant that each member of this commission has received from an important trade organisation in Germany a communication in which it is suggested that the protected names of drugs mentioned in the Norwegian pharmacopœia should be unaccompanied by their chemical synonyms. The idea that doctors and chemists should be kept in ignorance of the scientific names of drugs sold under a protected name was unanimously and without discussion rejected by the commission.

TEACHERS OF THE DEAF.

FROM the National Institute for the Deaf, Mr. A. J. Story writes:—"This Institute receives frequent enquiries from deafened persons for teachers of lip-reading, and some also from hearing persons who desire to be trained as teachers of this subject. It has also been represented to us that some who have leisure may desire to train in order to help the deafened in their district as a voluntary social service, while others not so favourably circumstanced may wish to teach professionally. We shall be glad to hear from any who are seriously interested in this matter. It is essential that those who teach the deaf should themselves have unimpaired hearing, should be of bright and active personality, and have received a good education. If sufficient numbers are forthcoming, this Institute will arrange short courses of training for teachers of this subject. The proposed courses will not qualify for teaching deaf and dumb or deafened children of school age, nor for service in schools or institutions under the Board of Education."

The address of the Institute is 2, Bloomsbury-street, London, W.C. 1.

THE PHYSIOLOGY OF MUSCLE AND NERVE.

THE advance in knowledge of the physiology of muscle and nerve has depended very largely on the invention of delicate apparatus. This has been wonderfully improved since G. J. Burch adapted the capillary electrometer and enabled Francis Gotch to get a record of the passage of a single impulse along a nerve. With modern galvanometers, amplifiers, and loud speakers, what was then demonstrated with difficulty and imperfectly can now make as much noise in the world as anyone cares to hear. Mr. Matthews gives in a handy volume [1] an account of the substantial progress made by Prof. E. D. Adrian and himself in the study of the nature of the nervous impulses which arise in consequence of artificial and natural stimulation. He adds short discussions on some of the relations of the body to electricity and on some aspects of the special senses. As a piece of popular scientific exposition the book is not very successful. It makes the fundamental mistake of appealing to the wonder and emotions of the reader rather than to his intelligent interest. In places, too, the physiology is unsound; it is misleading, for instance, to state without qualification (p. 27) that it is the nervous system which is responsible for the coördinated activity of the various parts of the body.

SIR BENJAMIN WARD RICHARDSON.

In a Chadwick lecture on Sir Benjamin Ward Richardson, delivered in London on Feb. 18th, Dr. J. D. Rolleston said that although it was little more than 35 years since Richardson's death, his valuable contributions to public health, his work, and even his name were little known to the present generation. He was born in 1828 at Somerby, in Rutlandshire, and after a varied experience as assistant to country practitioners, qualified at Glasgow in 1850. He subsequently came to London, and at the early age of 30 was already well known in the medical profession. His time was henceforth divided between consultant practice, laboratory research, especially in connexion with anæsthetics, delivery of lectures, and literary work, in which he was engaged until two days of his death in 1896. In 1867 he was elected F.R.S., and in 1893 he was knighted. He was the founder and editor of the first two journals in this country devoted to public health—viz., the *Sanitary Review and Journal of Public Health* (1855–59), and the *Social Science Review* (1864–66). In addition to biographies of eminent medical men or natural philosophers, which were published separately in 1901 under the title of "Disciples of Æsculapius," and clinical and experimental studies, the 12 volumes of the "Asclepiad" (of which the first appeared in 1862 and the remainder were published quarterly between 1884 and 1895, and were entirely written by himself) contained numerous articles dealing with various aspects of hygiene.

Richardson was one of the founders of the Epidemiological Society of London, took an active part in the proceedings of the Sanitary Inspectors' Association, and in 1882 founded the Model Abattoir Society. His lectures and addresses covered a wide field, including such subjects as a model city of health, dress in relation to health, woman as a sanitary reformer, national main drainage, and the healthy culture of the literary life. In 1878 he first made the proposal, which was not realised until 23 years after his death, for the establishment of a Ministry of Health. His most important lectures and addresses were those dealing with alcohol, in the scientific campaign against which he was a pioneer.

OFFICIAL YEAR BOOK OF LEARNED SOCIETIES.

The forty-eighth annual issue of this year book is much reduced in bulk owing to omission of the "Lists of papers read" at the various scientific and learned socieites which has been a feature of previous issues. This has enabled the publishers (Messrs. Charles Griffin and Co., Ltd.) to reduce the price of the book from 18*s.* to 10*s.*, and this should bring it within the reach of a wider circle of subscribers. The information contained has been checked by the officers of societies and departments concerned, and the year book can be relied on as a safe and comprehensive work of reference. The volume should be on every editorial table and on the shelves of every public library.

THE CARE OF SOLDIERS' FEET.

A small monthly magazine is issued in Germany at about a shilling, called *Kriegskunst*, which we may translate as "practical points about war," for the instruction of "other ranks." It gives instruction on map-reading, stories of gallant deeds and pictures of notable soldiers, and suggests how to deal with emergencies such as leaders of small parties must always be prepared for. Its pictures, "right and wrong," interest us most. Usually there are a dozen pairs of these, illustrating, for instance, the right and the wrong ways of climbing hills in snow, of training war-dogs, or of loading horses on trains. One of these series [1] is concerned with the care of the feet. It is wrong, says the instructor, to throw oneself carelessly on the ground at a halt on a route march, for the purpose of a halt is the care of the feet, when the malicious little demon (shown) who has put a pebble in one's boot can be sidetracked. How boots should and should not be dried is pictured, and the right and the wrong way of cutting toenails. These pictures may profitably be examined by those who are providing training manuals for the troops, for they tell in a moment what would otherwise need three lines of print, and, besides, the lessons are more easily memorised. Dissatisfied faces appear on the soles of the ill-used feet, whose owners are evidently among the less creditable of the soldiers delineated in the series.

AN EAST-END CLUB OPEN TO NURSES.

Mrs. B. L. Q. Henriques writes from the Bernhard Baron St. George's Jewish Settlement, Berner-street, Commercial-road, E.1:—"It may be of interest to those of the nursing profession attached to hospitals in the S.E., E.C., and E. districts of London to know that these beautifully equipped and comfortable premises are at their disposal for the purpose of a recreational club during off-duty time. The object of the club is to provide facilities for every sort of pastime for nurses, without any expense to them beyond a very small annual associate's fee. The club (which is already used by one hospital) is open daily from 9 A.M. to 5.30 P.M., thereby making it of use to both day and night nurses. The following are some of the activities available:—

Gymnastics, dancing, roller-skating, netball, badminton, deck-tennis, ping-pong, chess and draughts, reading-room, lending library, sewing-room, laundry, piano and violin practice, organ practice, glee singing, talks on art and music, and dramatic and debating section.

The changing-room, shower baths, &c., are available, as well as the common-room, garden, roof-playground and picture gallery which are open to members of the club. The restaurant and canteen may also be used.

The matrons of the various institutions within the radius are being notified of this scheme. It is hoped that the club will fill the need for a centre to which nurses can go for rest and recreation within reasonable distance of their hospitals, returning to them refreshed and with renewed vigour and inspiration. Application for membership should be made to me at the above address."

A FRAUDULENT YOUNG PERSON.

We understand that members of the medical profession are being approached by a correspondent named sometimes Millicent E. Aldridge and sometimes Mary Beale, the alleged reason for seeking pecuniary assistance being that she is awaiting an allowance from New Zealand, while she claims to be the daughter of a doctor. We understand that her correspondence is profuse, which accounts perhaps for the slip which allowed her to make identical applications for aid to the Royal Medical Benevolent Fund under her two different signatures, applying to the Fund personally as Mary Beale "on behalf of her father Dr. Thomas Beale," and to a member of the committee of the Fund in the same words as Millicent Aldridge. This led to the Fund bringing the matter before the Charity Organisation Society, whose information is clear, stating that the applicant for help is a young woman, a notorious begging letter writer, with the real name of Jean Atherton. The Society strongly urges all who are approached by her to immediately communicate with the police.

Croydon Hospital Nurses' Home.—Lady Brown, wife of Sir Robert Brown, chairman of Croydon Hospital, recently opened the Charles Heath Clark memorial home for nurses in connexion with the hospital. The home was formerly three houses which have been bought and reconstructed at a cost of £20,000, one-half of which has been contributed by the executors of Mr. Clark, who was twice mayor of Croydon. There are 51 bedrooms.

ADDRESSES AND ORIGINAL ARTICLES

THE PATHOLOGY AND TREATMENT OF ANÆMIA.

BY L. J. WITTS, M.D. MANCH., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO GUY'S HOSPITAL; WILL EDMONDS CLINICAL RESEARCH FELLOW.

LECTURE I.

THE ERYTHRON IN HEALTH AND DISEASE.*

> "As regards the relative value of clinical and post-mortem observation in the diagnosis of cases of anæmia of doubtful nature, there is in my experience no doubt. For purposes of diagnosis I would rather see a case of severe anæmia during life than base my diagnosis on any blood changes or other features that might be presented in the form of reports."
>
> WILLIAM HUNTER, 1923.

THE original duty of the Goulstonian lecturer was to dissect the body and to demonstrate his dissections. In the same spirit I shall try to draw a simple picture of that interesting tissue which is constituted by the red blood-cells and their precursors, and to give examples of its reactions in health and disease. Boycott has suggested the term *erythron* to comprise the circulating red blood-cells and the cells from which they arise. This term is valuable not only because of its brevity, but also because it emphasises the functional unity of the red cells and their precursors. The erythron may be aptly compared with an organ such as the skin. Just as in the skin we recognise the strata germinativum, mucosum, granulosum, lucidum, and corneum, so in the erythron we must think of the primitive cells evolving through megaloblast, normoblast, and reticulocyte to the mature erythrocyte. The interstitial tissue of the erythron is represented by the plasma, and by the fat and reticulum of the bone-marrow. Few people have a conception of the size of the erythron. The volume of the marrow cavity is estimated at 1400 c.cm., the total volume of the circulating blood at 4000 to 8000 c.cm. Even when no account is taken of the plasma, the size of the erythron can hardly be less than 2500 c.cm., so that it is an organ considerably larger than the liver. Escaping from the vessels at autopsy, or lying hidden in the recesses of the bones, it has too often escaped the attention of the morbid anatomist, and the pathology of the erythron remains to be written.

Boycott has shown that the erythron may, like other organs, undergo atrophy or hypertrophy, the one from increase of the oxygen tension, the other from its diminution, and he regards Osler's disease, polycythæmia rubra, as an obscure hyperplasia or perhaps a veritable tumour of the erythron. Following his lead we may speak of the congenital dystrophies of the erythron, the best known of which is acholuric familial jaundice, in which an abnormal and fragile corpuscle is transmitted from generation to generation. Less familiar to us but of the same hereditary type are the sickle-cell anæmia of negroes and the rare ovalocytosis. The anæmias which follow hæmorrhage or the lysis of the corpuscles by chemical or bacterial poisons are obvious examples of trauma to the erythron and are repaired according to the ordinary rules of pathology. Just as other organs are damaged by infections and toxæmias, undergoing parenchymatous degeneration or fatty change, so also the erythron with consequent anæmia. Familiar examples are the anæmia of typhoid fever or of chronic nephritis. Not only is the circulating blood impoverished, but the marrow is hypoplastic. In long-standing cachexias the hypoplasia may terminate in a peculiar gelatinous degeneration of the marrow, while a more acute poisoning, such as occasionally follows the injection of salvarsan, leads to complete aplasia of the bone-marrow. The erythron may be the seat of tumour metastasis, or be compressed and almost obliterated by the proliferation of the white cells in leukæmia.

Erythrogenesis and Erythrolysis.

So far we have applied to the erythron the same principles as we should apply to the consideration of the diseases of any other organ, and have discussed the banal effects of trauma, infection, and so on, effects which we are accustomed to describe as secondary or symptomatic anæmia. Most organs, however, have their special diseases, as examples of which I would cite Bright's disease of the kidneys, the cirrhoses of the liver, or the peptic ulcers of the stomach and duodenum. To understand these diseases an intimate knowledge of the structure and function of the organ at fault is necessary. It is not otherwise with the erythron, and if I seem to spend long in discussion of its structure and function, it is because I feel that such knowledge is essential for the understanding of its diseases. If we pause to wonder why the blood contains roughly 100 per cent. of hæmoglobin and 5,000,000 red cells per cubic millimetre, and how it is held constant at this level by the activity of the bone-marrow, we shall soon find ourselves engaged in speculations that seem to lead us far from the immediate problems of medicine. The hæmoglobin content of the blood is dependent on the oxygen tension of the inspired air, and on the need of maintaining a constant internal environment for the organism. The size and number of the red cells are such as to ensure the best utilisation of the hæmoglobin store of the organism, especially in the passage of the blood through the capillaries.[7]

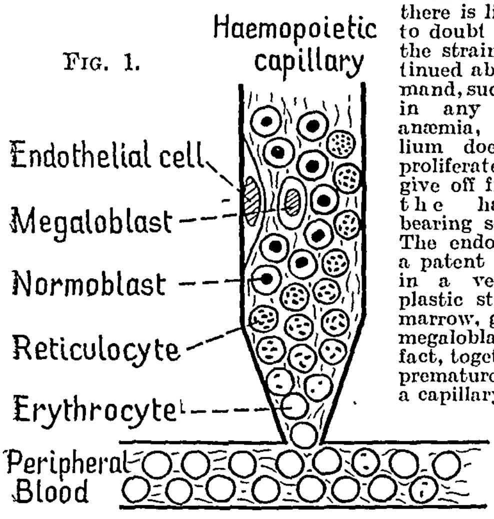
Red marrow is confined to the cancellous bones and the ends of the long bones. The vascular system of the bone-marrow is closed and the whole of the erythron, including the most primitive cells from which it arises, is intravascular. The capillaries of the marrow not only serve to maintain the circulation, but they also have a dual function in erythrolysis and erythrogenesis. The endothelial cells of the sinuses are phagocytic like those of the liver and spleen. Connecting the sinuses are the intersinusoidal capillaries in which the red cells are formed intravascularly, in contrast to the white cells which arise outside the vessels and migrate into the circulation when they mature. The endothelial cells lining the intersinusoidal capillaries give rise to the earliest megaloblasts by mitosis into the lumen. Successive divisions of the megaloblasts produce the erythroblasts, normoblasts, reticulocytes, and thus the red cells of the circulating blood. Developing within the capillary, the red blood-cells dilate the lumen and stretch the wall, but the capillary does not normally open to the circulation until the red cells are mature. This is because the membrane of the young cells is sticky and they adhere to one another. The stickiness persists till about the time when the reticular substance disappears from the cell. The plasma then filters between them, and they are swept into circulation. Just as the capillaries of the muscles and the kidneys vary greatly in activity with the activity of the tissue they supply, so also the capillaries of the marrow. In the marrow they offer not merely a reserve capillary bed, but the potentiality of an enormous hyperplastic response.

---

* The first Goulstonian Lecture for 1932 delivered before the Royal College of Physicians of London on March 1st.

> “ In the normal, non-hyperplastic, unstimulated state, the erythroblastic level is the one from which the vast majority of the red cells come. Erythroblasts proliferate rapidly, and in the normal marrow are the youngest type of cell to be seen in all recognisable foci of red blood-cells. One megaloblast is conceivably sufficient to form the basis of an extensive focus of erythroblasts, which may be able to multiply quite indefinitely under normal conditions. Thus the endothelial cells not being called upon to augment the foci of developing red cells which can be maintained by the erythroblasts themselves, or at most only being stimulated to an occasional differentiation of megaloblasts from an isolated endothelial cell, commonly appear in the older, inactive phase. . . . Normal marrow has a considerable store of normoblasts which can then pass through the next phase of their maturation into erythrocytes by the extrusion of their nuclei. But there is little reason to doubt that under the strain of a continued abnormal demand, such as occurs in any secondary anæmia, endothelium does actively proliferate, and does give off free cells of the hæmoglobin-bearing series. . . . The endothelium of a patent sinus may, in a very hyperplastic state of the marrow, give rise to megaloblasts. This fact, together with a premature opening of a capillary, may explain the method by which immature cells get into the circulation.” [5]

FIG. 1.



Schematic diagram of the erythron.

During the maturation process the nucleated erythroblasts elaborate hæmoglobin and they lose their nuclei before becoming adult red cells. Except for a small fraction of reticulocytes, which in health does not exceed 1 per cent., the circulating erythrocytes are all mature cells. The mature red blood corpuscle is as highly specialised and as “ dead ” as the stratum corneum of the skin. The reticulocytes are so called because vital stains render visible in them a network or reticulum, which is really a precipitate of remnants of the basophil cytoplasm of the immature cell. Reticulation is identical with polychromasia, though the vital stains display the basophilia better than eosin-methylene-blue ; punctate basophilia is a modification of the same phenomenon. In the blood stream, or at body temperature in vitro, reticulocytes ripen into adult corpuscles, the process taking from a few hours to a few days, according to the amount of basophil substance they contain. When the delivery of red cells into the circulation is increased, as happens after a considerable hæmorrhage or in the regenerative phase of anæmia, the percentage of reticulocytes rises and may reach 50 per cent. or higher. Conversely, when the delivery of red cells into the circulation is diminished, as happens with artificial plethora in animals or in non-regenerative anæmia in man, the number of reticulocytes falls below the level of health. Enumeration of the reticulocytes is therefore a valuable method for determining the rate of blood formation.

When blood formation is excessively active, the more immature cells, normoblasts and megaloblasts, enter the circulation. Whenever the bone-marrow is hyperplastic nucleated red cells may appear in the peripheral blood ; for it is then easy for them to be washed into the blood stream, especially when hæmopoiesis is not confined to the intersinusoidal capillaries and invades the sinuses. Hyperplasia of the marrow is by no means synonymous with increased blood formation, the reaction is often abortive and the cells fail to mature. This is a very important fact which I shall discuss in full later. I must now emphasise that nucleated red cells are a sign only of hyperplasia of the bone-marrow and are not evidence of increased blood formation unless they are accompanied by an increased number of reticulocytes. The coexistence of nucleated red cells and a reticulocytosis is of course unimpeachable witness of an accelerated delivery of red cells into the circulation, for the reticulocytes will ripen into adult red cells in the blood stream.

Having followed the red cells to their entrance as mature erythrocytes into the circulating blood, we must now inquire into their ultimate fate. Their life has an average duration of 30 days and it is not a whit less hard than that of the superficial cells of the skin. Anyone who has seen cinematograph films of the capillary circulation must have been impressed by the wear and tear to which the red cells are subjected. In Peyton Rous's dramatic words, they are finally threshed to bits. The terminal disintegration of the worn-out red cells can be watched under the microscope with the aid of a warm stage :

> “ A red cell puts out a long process and thereby becomes the so-called poikilocyte. At first the process does not move, then it begins to vibrate slowly, then faster and faster. This vibration marks the beginning of fragmentation. As the process vibrates, it gradually becomes thinner and thinner at some point and then separates. If the thinned-out place is at the base of a long process, the fragment becomes a rod, often looking like an irregular but yellow bacillus ; if near the tip, it becomes a round or oval body. We have seen every variation in size and shape of these processes, up to an actual division of a red cell into two equal parts. . . . We interpret a poikilocyte as the first stage in the process of fragmentation, and the microcyte, in many instances, as a red cell reduced in size after some of its cytoplasm has broken off.” [6]

Exercise, by increasing the wear and tear of the red cells, accelerates their disintegration. In anæmia the cells produced by the bone-marrow are less perfect and more easily worn out. For both reasons rest is an essential measure in the treatment of anæmia. I do not think lysis of the red cells occurs in health, their ultimate fate is always fragmentation. The fragments are taken up by the phagocytes of the reticulo-endothelial system and digested into simpler components. Iron and bilirubin are the most familiar of the disintegration products. It is well established that when large numbers of red cells are suddenly destroyed, the bilirubin in the blood and the excretions is increased and iron is deposited in the liver and other organs. About this there is not a shadow of doubt. On the other hand it is a serious error to argue in the reverse direction and to conclude that hyperbilirubinæmia and hæmosiderosis are always the result of increased blood destruction. Indeed the estimation of the rate of turnover and destruction of red cells is beset with difficulties.

The Dynamics of Blood Formation.

A fundamental question of hæmatology is the decision whether an anæmia is due to diminished blood formation or to increased blood destruction. It is as important to decide this as to decide whether jaundice is obstructive or non-obstructive, or whether anuria is due to suppression or retention. Yet I do not exaggerate when I say that we have no reliable criteria for this purpose. It is desirable that the difficulties should be appreciated, for progress is much retarded when obscure anæmia is attributed without valid evidence to unproved hæmolysis or toxic depression of the functions of the marrow. Hæmatology will not be an exact science until we can measure the number of red cells, which enter or leave the circulation in the 24 hours, with the same accuracy as we can measure the protein metabolism or the work of the heart.

One of the breakdown products of hæmoglobin is the iron-free pigment bilirubin which, after circulating in the blood, is excreted in the bile and converted in the intestine into stercobilin, the form in which it leaves the body. The output of bilirubin can be accurately determined by estimating the stercobilin of the fæces: indirect evidence can be obtained from the bilirubin content of the blood and the urobilin of the urine, though the results are then affected by the functional condition of the liver and kidneys. Physiological experiment shows that there is a fundamental fallacy in trying to gauge the rate of blood destruction from the bilirubin output. When blood is destroyed, the bilirubin obtained from it is not quantitatively excreted. Bilirubin is not a waste product and much of it may be retained to be used over again in the manufacture of fresh red cells. The proportion retained is not a fixed quantity but depends on the needs of the organism.[25] From physiology we must conclude that the turnover of red cells might be increased without any change in bilirubin excretion.

The study of cases of anæmia brings to light even greater difficulties. In pernicious anæmia the excretion of bilirubin derivatives may vary from normal to 20 times the normal in different patients, who show the same profound degree of anæmia and are otherwise indistinguishable. Both Whipple and Jedlicka have calculated the level of the blood exchange in pernicious anæmia on the assumption that the bile-pigment excreted per diem was derived from the breakdown of red cells. Jedlicka calculated that the excretion of bilirubin derivatives may be 13 times as high in a patient with pernicious anæmia as in health, and that in extreme instances such a person must renew the whole of his blood in 21 hours. This is a reductio ad absurdum, for it is impossible for the blood to be renewed in so short a time.

In a subsequent paragraph I shall discuss recent work which proves that hæmolysis plays a secondary part in pernicious anæmia and that the primary cause of the anæmia is a retarded delivery of red cells into the circulation, in fact a much reduced turnover of red cells. It is profitable to compare pernicious anæmia with another metabolic disease, diabetes mellitus. Hyperglycæmia, deposits of glycogen in the heart and kidneys, and excretion of sugar in the urine do not mean that carbohydrate metabolism is accelerated but the very reverse; they are signs of inability to metabolise glucose in the absence of insulin. Similarly in pernicious anæmia hyperbilirubinæmia, deposits of iron in the viscera, and increased excretion of bilirubin derivatives are not because the blood breakdown is accelerated, but because the bone-marrow is unable to use these metabolites in the manufacture of fresh red cells, when the hæmatinic principle, which is elaborated in normal digestion and stored in the liver, is not supplied. Hyperbilirubinæmia and increased excretion of bilirubin derivatives thus come to be associated with a diminished blood exchange. I must leave further discussion of pernicious anæmia till later, but I think there is no doubt that on the one hand the turnover of red cells may be increased without any change in bilirubin excretion, on the other hand that the excretion of bilirubin derivatives gives no reliable information as to the rate of blood exchange.

Estimations of the number of reticulocytes have added much to our knowledge of the rate of blood formation in disease, but this test must not be used uncritically, and it needs collateral support. Reticulocytes appear in the blood stream when the marrow is irritated by a variety of substances, such as shellac and colchicin, and marrow irritation must be distinguished from a real increase of red cell production. I have seen reticulocyte counts of 6 per cent. in aplastic anæmia, though the absolute number was small, and this is not surprising when we remember that a few remnants of hyperplastic marrow are usually left in this disease. An increased delivery of red cells into the circulation may be unaccompanied by any rise in the number of reticulocytes, as when a transfusion is given at the beginning of liver treatment in pernicious anæmia.

I have stated these difficulties frankly because they have been so much ignored, but I cannot promise to solve all of them, for the simple reason that there are not enough facts. If we know little about the pigment metabolism in health and disease, we know still less about the other breakdown products of the red cell. The biochemist has devised exquisite chemical analyses of the plasma to ascertain the functions of the kidneys, the liver, and the pancreas, but until recently he has overlooked the chemistry of the erythron itself. The iron content of the viscera is still too often deduced from the microscopical appearances and the ferrocyanide reaction, though these methods were proved fallacious at the beginning of the century. The chemistry of the marrow is unexplored. Happily this has now become one of the active growing points in medical progress. We already known that the loss of the nucleus in the development of erythroblasts into erythrocytes increases the excretion of uric acid[23]; that the reticulocytes contain nuclear phosphorus which disappears when they mature[16]; that there are characteristic changes in the free iron[24] and the lipoids[19] of the serum in the different phases of anæmia. To such researches we look for help in the dynamics of blood formation. In the meantime the physician will do well to remember the wise words of William Hunter with which I have prefaced this lecture. Anæmia must be studied in the patient, and not merely in a droplet of his blood. The erythron does not work in isolation, but in close dependence on the other organs of the body and in subordination to the whole. A blood picture, or indeed a marrow picture, is only a symptom; it may appear as the result of very different causes, and it demands for its explanation the whole history and present state of the patient.

Hæmopoiesis and Anhæmopoiesis.

We see the importance of these points when we study the behaviour of the erythron in disease. Morphologically the changes are simple, consisting on the one hand of hypoplasia or aplasia of the bone-marrow, on the other of hyperplasia. Two degrees of hyperplasia may be described. Usually the number of erythroblasts is much increased, and the red marrow spreads into the shafts of the long bones, [illegible] and normoblasts, with [illegible] which gives [illegible] of uric acid. The [illegible] appears to be the [illegible] in health, [illegible] anæmia the [illegible] of the normal

The [illegible] s of the [illegible] simpler [illegible] miliar [illegible] lished [illegible] ry of the disease. Finally, Filo has shown the signs of increased activity of the bone-marrow, reticulocytosis, and the rapid rise of red cells, occur at a time when the stercobilin excretion till considerably raised, and that it never happens t the increased stercobilin excretion disappears re the signs of regeneration of the red cells are n.

do not wish to deny that hæmolysis occurs in nicious anæmia. There is in vitro evidence[3] undue mechanical fragility of the megalocytes, d it is likely that these abnormal cells are not apted for long survival in the circulating blood. ie pathologist regards the phagocytosis of red lls and their debris as a hall-mark of pernicious æmia, and it is rarely if ever absent in the severer ages of the disease. But this hæmolysis is secondary the dysplasia of the bone-marrow, and it is inconivable that there is so much hæmolysis as to account r all the bilirubin put out. The quality and istribution of the hæmosiderosis of pernicious næmia is quite different from that of true hæmolytic næmias such as acholuric jaundice. Some other xplanation than hæmolysis must be found for the yperbilirubinæmia and hæmosiderosis which are so constantly associated with the megaloblastic degeneration of the bone-marrow in pernicious and allied anæmias. As I have already stated, the disturbance of iron and pigment metabolism is probably the result of diminution of the anabolic activity of the bone-marrow. No such accumulation of iron or pigment occurs when erythrogenesis is arrested at the normoblastic level or in aplastic anæmia. It is in some way conditional on the megaloblastic level of dedifferentiation. I feel that the hæmatinic principles, which are necessary for the metabolism of megaloblast into normoblast, must also control the metabolism of iron and pigment, and that therefore the metabolism of iron and pigment is deranged contemporaneously with the megaloblastic degeneration of the bone-marrow, because both are the result of a common cause, and not because one is the effect of the other.

I have devoted considerable time to discussion of the mechanism of pernicious anæmia because it the best-studied of all the anæmias, and because principle of dysplasia of the bone-marrow is of amental importance in the classification of the nias. Tentatively we might divide the anæmias two broad groups: first, those with hypoplastic lastic marrow, and, second, those with hyper- marrow. Then we must subdivide anæmia hyperplastic marrow according as the hyperplasia ive or *hæmopoietic*, and passive or *anhæmopoietic*. anhæmopoietic or maturational anæmias form ay opinion the most important of all the groups iseases of the erythron, and I propose to devote whole of my second lecture to them. Before ncluding this lecture on the physiology and pathogy of the erythron, I should like to say a few words st about splenomegaly in anæmia, and then about he size of the red cells in anæmia.

Splenomegaly.

With the exception of aplastic anæmia, all the chronic diseases of the blood-forming organs tend to produce enlargement of the spleen, whether they involve initially the red cells, white cells, or platelets. On this account the coexistence of anæmia, leucopenia, and splenomegaly never justifies an immediate diagnosis of splenic anæmia, but for lack of further investigation and observation I have several times seen aleukæmic leukæmia, essential thrombopenia, and simple achlorhydric and allied anæmias masquerade under this too comprehensive diagnosis. Splenic anæmia is in reality a rare disease. Enlargement of the spleen and anæmia are more commonly the result of an independent disease of the blood-forming organs than of splenic anæmia. It is now becoming accepted that splenic anæmia is always the result of high pressure in the portal circulation,[18] and that in the great majority of cases this is due to primary disease of the liver, though the morbid change in the liver may be visible under the microscope only.[15] The anæmia is the result of the raised portal pressure, as has often been shown in experimental animals.[21] Identical anæmia occurs in Laennec's cirrhosis of the liver.[17] It is unwise to diagnose splenic anæmia in the absence of signs of raised portal pressure or of liver damage without the most careful circumspection.

The Size of the Red Cells.

If splenic anæmia has often been diagnosed too freely, the reverse mistake has been made about pernicious anæmia, which some hæmatologists have tried to preserve in almost sacred isolation. Pernicious anæmia is not a unique disease, and similar changes occur in the blood in a variety of conditions. The anæmias of sprue and of *Bothriocephalus latus* infestation are closely akin to pernicious anæmia. Our President has described instances of megaloblastic alteration of the bone-marrow in the crises of acholuric jaundice.[4] In both hæmopoietic and anhæmopoietic anæmia the hyperplasia of the marrow may be normoblastic or megaloblastic, and of this fact I shall give many examples in my subsequent two lectures. The appearance of megaloblasts in the marrow and of megalocytes in the peripheral blood is not a specific disease, but a reaction which may occur in a host of different conditions. A disease is "the whole consequence of a conflict between man or animal and the noxious agencies in his environment,"[26] and in the definition of disease entities the clinical and biological features must always be more important than the blood picture.

The reactions of the erythron, which I have described as aplastic, normoblastic, and megaloblastic, can be roughly correlated with variations in the size of the cells of the peripheral blood. The size of the red cells is estimated either by the Price-Jones curve, which is based on the diameter of several hundred red cells, or by the hæmatocrit. The Price-Jones curve has the great advantage of showing the degree of anisocytosis, which is not revealed by the hæmatocrit. The hæmatocrit measures the volume of the cells and may detect changes which are not evident from measurement of the diameter alone. The red cells maintain a very constant size in health, their coefficient of variation being less than one-third of that of the red cells or hæmoglobin. The size of a man's red cells, measured under standard conditions, is as characteristic and permanent as his finger-prints or his electrocardiogram. In disease the mean diameter of the red cells may change and the degree of anisocytosis increase. Price-Jones has recently constructed a curve which embraces all the possible variations in size of healthy red corpuscles. Cells falling outside this ideal curve are pathological. In pernicious anæmia the mean diameter of the red cells is increased and many fall to the right of the ideal curve. They are pathological megalocytes, indicative of abnormal erythropoiesis. On complete and successful treatment with liver, the curve shifts back to the normal position and the pathological megalocytes disappear. In chronic hæmorrhage, and in simple achlorhydric and allied anæmias, the mean diameter of the red cells is diminished and many of the cells fall to the left of the ideal curve. They are pathological microcytes, and their appearance likewise is suggestive of abnormal erythropoiesis. Here the curve returns to the normal position and microcytes disappear on successful treatment with iron.

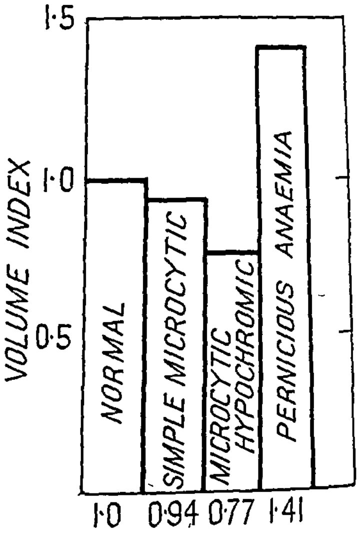
Curves identical with those of pernicious anæmia have been obtained from cases of *B. latus* infection,[11] sprue,[11] chylous diarrhœa,[12] and the hæmolytic anæmia of pregnancy,[20] and it would appear that they can be obtained whenever there is megaloblastic degeneration of the marrow. As regards the microcytic anæmias, it is noteworthy that there is microcytosis both in chronic hæmorrhagic anæmia and in simple achlorhydric anæmia, two conditions in which there is normoblastic hyperplasia of the marrow. The whole story of these variations in size of the red cells is not yet told and the time is hardly ripe for generalising. Price-Jones and his associates have shown that the curves obtained in certain non-Addisonian hæmolytic anæmias resemble that of Addison's anæmia in the increase of the mean diameter of the cells but differ from it in the symmetry of the curve and the absence of anisocytosis.[9] Again, when we consider the appearance of pathological microcytes in the blood, we must remember that some of them may be fragmented normocytes and not preformed microcytes. Finally, the reactions of the erythron are not always pure, and both megaloblastic and normoblastic reaction may occur simultaneously, so that pathological megalocytes and microcytes appear in the same blood. Even more often, a megaloblastic or a normoblastic reaction is accompanied by more or less aplasia of the marrow. With these cautions in mind, we may make the broad generalisations that megaloblastic hyperplasia of the marrow, whatever its cause, is associated with a *megalocytic or macrocytic anæmia.* Normoblastic hyperplasia of the marrow, whatever its cause, is associated with a *microcytic anæmia.* Aplasia and hypoplasia of the marrow, inasmuch as they produce a general depression of the erythron rather than a disturbance of the mechanism of erythropoiesis, cause little change in the size of the red cells and are associated with a *normocytic anæmia.*

This method of classifying the anæmias has been very fully developed by Wintrobe, Haden, and others with the hæmatocrit technique. Wintrobe's cases fell into the following four groups[29] :—

1. The *macrocytic* anæmias, which include cases of pernicious anæmia, sprue, and the pernicious anæmia of pregnancy, and which are characterised by an increase in the mean size and hæmoglobin content of the red corpuscles.
2. The *normocytic* anæmias, which include cases of acute blood loss, malarial infection, and anæmia of the aplastic or semi-aplastic type, and which are characterised by a reduction in the red cell count without any change or at most only a slight increase in the size and hæmoglobin content of the red corpuscles.
3. The *simple microcytic* group includes the most commonly observed forms of anæmia, the anæmia associated with chronic infections such as bronchiectasis and typhoid fever, chronic intoxications such as cardiorenal disease, and carcinomata in which there is no bleeding There is a moderate reduction in the corpuscular volume and hæmoglobin, but at no time is this decrease as great as the reduction in the number of red cells.
4. The *microcytic, hypochromic* group, which includes the anæmia of chronic hæmorrhage, hookworm infestation, and simple achlorhydric and allied anæmias, is distinguished by a marked reduction in the volume of the red corpuscles and a decrease in their hæmoglobin content, which is even more marked than the decrease in size.

Very similar results were obtained by Haden, whose data I have used for Fig. 3. More work must be done before we can properly correlate the size of the red cells with the changes in the marrow. From what we already know of the marrow in infections and toxæmias, it seems likely that in group 3 there is a varying mixture of normoblastic hyperplasia and aplasia, which explains its position between the normocytic anæmia of aplasia and the frank microcytic anæmia of normoblastic hyperplasia. It may be noted in passing that the red cells never become more saturated with hæmoglobin than they are in health, and that a high colour-index is always a sign of megalocytosis. On the other hand, it is quite possible for the corpuscular concentration of hæmoglobin to fall, and a low colour-index may be due to low hæmoglobin concentration or hypochromia, as well as to microcytosis.

FIG. 3.



Volume index of red cells in health and in anæmia.

A given lesion may always produce the same change in the erythron—for instance, hæmorrhage always leads to a normoblastic reaction—but we shall not be surprised to find that the same agency, working under different conditions or with different intensity, may at various times produce any of these reactions For example, sprue may begin with a normoblastic reaction associated with a microcytic anæmia, progress to a macrocytic anæmia with megaloblastic marrow, and terminate in aplastic anæmia. Nor shall we expect the reaction always to be pure in type any more than tumours are sharply divisible into innocent and malignant. The anæmia of gastric achlorhydria sometimes has features of both normoblastic and megaloblastic response and the tropica anæmias show a mixture of megaloblastic reaction and aplasia. All this must persuade that a blood picture is not a disease, and in discussing anæmias in the two subsequent lectures, I shall work as far as possible on a clinical and ætiological basis.

ELECTROCARDIOGRAPHIC CHANGES DURING TREATMENT OF SEVERE DIABETES.

BY K. SHIRLEY SMITH, M.D., B.SC., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN AND PHYSICIAN IN CHARGE OF THE CARDIOGRAPHIC DEPARTMENT, CHARING CROSS HOSPITAL; PHYSICIAN TO OUT-PATIENTS, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS;

AND

R. A. HICKLING, M.D. CAMB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, CHARING CROSS HOSPITAL; PHYSICIAN, ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.

THE present investigations concern electrocardiographic changes during the treatment of severe diabetes. The experimental method is outlined, and the results are tabulated and described. Serial electrocardiograms from typical and special cases are reproduced. The metabolism of the diabetic heart is contrasted with that of the normal heart and finally the possible mechanisms underlying the electrocardiographic changes occurring in diabetes are considered.

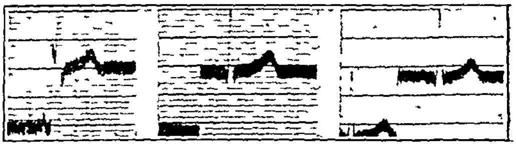
It was thought that the metabolic and arterial disorders occurring in diabetics might either independently or in conjunction be reflected in the electrocardiogram. In the course of treatment by diet or diet and insulin the defects of metabolism are largely abolished. Nor are ischæmic processes consequent upon, for example, early atheroma necessarily ineradicable, for Aschoff has demonstrated that this intimal degeneration is, up to the stage of fatty deposition, a reversible process. It was therefore considered most profitable to study electrically the heart in diabetics undergoing treatment with the aim of revealing modifications in the electrocardiogram.

One or two studies upon lines contiguous to these have already been made. Blitzsten and Schram made an electrocardiographic examination of 70 diabetics of all grades. In only six patients was an attempt made to trace the electrical changes occurring during treatment. Notching of the Q R S complex was found in 30 per cent. of the group, and all the investigations pointed to an increased voltage in severe hyperglycæmia, the amplitude of the deflections falling as the blood-sugar diminished. No mention of the T-waves is to be found in their paper. An electrocardiographic study of 123 diabetics was made by Hepburn and Graham who found that in 56 there were significant electrocardiographic changes, but in only 23 of these patients was more than one record obtained. No attempt was made by these authors to trace successive changes during stabilisation by dietetic or insulin treatment, nor were tracings published by them. Other electrocardiographic investigations such as those of Weichmann and of Middleton and Oatway have been concerned chiefly with hypoglycæmia, while Stepp and Parade have studied the influence of insulin rather than the effect of diabetes itself. Further reference will subsequently be made to these studies.

EXPERIMENTAL METHOD.

The patients selected for observation were those suffering from a severe grade of diabetes. In all the patients at the time of the first electrocardiogram there was considerable hyperglycæmia with glycosuria and variable degrees of ketosis, but actual or threatened coma was never present. In no case was there evidence from the history or the physical examination of cardiac or other additional disease, with the exception of variable degrees of arterial thickening and hypertension which were common among the older patients. Nor were patients showing glycosuria of doubtful origin, such as renal glycosuria, included. The initial tracing was usually taken just after admission to hospital and always before any dietary or other treatment had started. Subsequent records were obtained at intervals ranging from two to seven days, and usually after discharge from hospital further electrocardiograms were taken at intervals of two or three weeks, and later, months.

FIG. 1 (Case 6).



Successive records (lead I.) showing standardisation and increased amplitude of T-wave after one week of treatment.

The experimental group consisted of 20 patients whose ages ranged fairly evenly from 10½ years to 63 years. The duration of the illness in some of them could not be accurately ascertained as investigations were begun at the time of the first diagnosis. In others, presenting themselves with severe uncontrolled diabetes, the disease had started years previously but had never been adequately treated.

Full clinical and biochemical data were obtained in each case. For each patient the state of the urine was recorded both at the time of every electrocardiogram and during the intervals. Every care was taken to procure accurate and comparable electrocardiograms, with the minimal resistance in the patient. The usual standardisation of 1 cm. deflection for one millivolt was actually recorded for each lead in the majority of electrocardiograms (Fig. 1). These serial records were subsequently studied in relation to the changing clinical condition of the patient.

RESULTS.

The patients investigated are listed in the Table in order of age, starting with the youngest. They are arbitrarily separated into two age-groups, those below the age of 40, and those above. It is seen that in the earlier age-group the duration of the disease had been generally one year or less, while in the older patients investigated the disease had been

Dr. Robert [illegible] Library
[illegible] Medical College

present usually for two years or more. The alterations in the component parts of the electrocardiogram are shown in each instance. The first three columns are self-explanatory. Absence of change is throughout indicated by a dash. The notation employed in regard to the T-waves is as follows: a slight increase in amplitude in successive electrocardiograms is indicated by (+), while pronounced increases are shown as (++). The sign (+) is also employed to denote the abolition of a previously inverted or diphasic T-wave, while (++) indicates the appearance of an upright T-wave in the place of one previously inverted or diphasic.

Alterations in the P-wave.—Where any change during treatment was observed it was a diminution. This was found in 6 of the 20 patients

Alteration in P-R interval.—No alteration in the P-R interval was discovered in any case. In some instances it was difficult to compare accurately the P-R interval on account of the somatic tremor present in the earlier electrocardiograms.

Table showing the various changes occurring during treatment in the electrocardiograms of a series of 20 diabetic patients.

* Alteration in P–R intervals: Nil in each case.

Alteration of Q R S complexes.—Slurring or splintering of the Q R S complexes was observed in five patients, both young and old (Cases 7, 8, 12, 13, and 16). In the first three of these (the younger patients) this deformity of the Q R S complexes either diminished or disappeared.

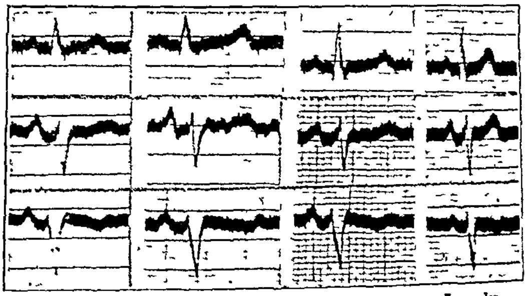
Alterations in the T-wave.—Taking these end-deflections as a whole it was noticeable that modifications occurred more readily in lead III. than in the other leads, and more readily in lead II. than in lead I. Further, it was found that T-wave alterations, whichever lead was considered, were far commoner in the younger age-group than among the older patients, while if any variations in the amplitude of the T-wave were found in the latter group, they were always slight.

The alteration most commonly observed in the T-wave during treatment was an increasing amplitude. This occurred mostly in leads I. and II. (Fig. 2). Another frequent modification was the substitution of an upright T-wave for one previously diphasic or inverted, this change being seen very often in lead III. and occasionally in leads I. and II. (Fig. 3, lead III.).

Changes in T in lead I.—Of the series of 20 patients only two showed initial inversions of T_1 which later became upright (Figs. 3 and 4). In these cases the restoration of a normal T-wave was gradual, occupying about seven weeks in Case 3, and over three months in Case 11. Increasing amplitude of T_1 during treatment was found in seven other patients.

Changes in T in lead II.—In lead II. also, only two patients showed inversion of the T-wave; these were the patients already mentioned in whom T_1 was also inverted. Treatment restored T_2 to a normal sense and shape more readily than in the case of T_1, the change occupying a week or two (Figs. 3 and 4). Increasing amplitude of T_2 during treatment was found in eight other patients.

FIG. 2 (Case 7).



Female diabetic, aged 32. First ECG taken before treatment. Successive records during treatment show, in leads I. and II., increasing amplitude of T-waves, which are finally considerably increased.

Changes in T in lead III.—In 9 of the 11 patients under the age of 40, and in 11 of the whole series, changes took place in T_3 during treatment. This change in seven instances was the substitution of an upright T-wave for one previously diphasic (Fig. 4). In the remaining four patients, increasing amplitude of an upright T-wave or the conversion of a frankly inverted T-wave to the upright form were noted. It was observed that these alterations in T_3 occurred readily, often within a few days of the institution of treatment. The form of T_3 was always apt to vary for no obvious reason (Fig. 4).

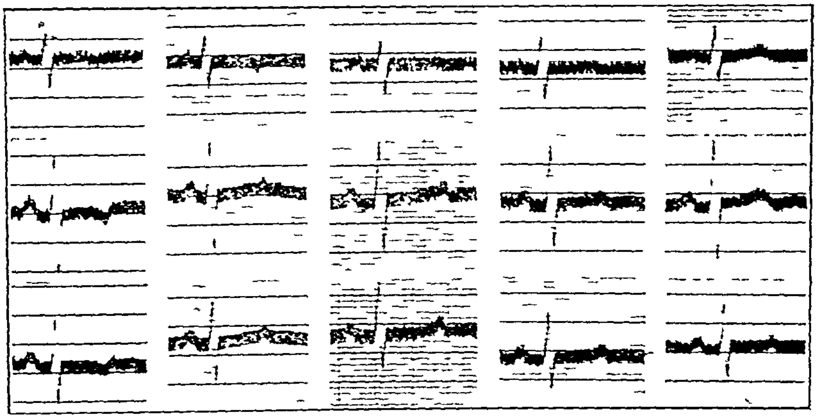
Effect of insulin.—In several patients the changes in the T-waves described above developed progressively, and later, after a few weeks, some diminution of the amplitude of the waves would occur (Figs. 1 and 5). The secondary changes seemed possibly to bear a relation to the use of insulin which is known to cause a reduction in the amplitude of the T-wave. Further reference to this point will be made below.

COMMENTARY.

Among the complications to which diabetics are subject, arterial disease is one of the most formidable. The association of these diseases has been recognised for the past 50 years, but it is not generally appreciated how intimately they are inter-related. Joslin (1928) estimates that arterio-sclerosis in its various forms is responsible for half the deaths in diabetics to-day, while Allen claims that it is demonstrable in every diabetic past middle life in whom glycosuria has been present for ten years or more. Studies of patients over 40 years of age by Bowen and Keonig showed that nearly two-thirds were afflicted with arterial disease. A corresponding proportion of a group of 53 diabetics observed by Heitz gave evidence of early arterial degeneration on oscillometric examination.

But it is not only in the older diabetics that arterial isease supervenes. Shepardson in a radiological nvestigation of 50 patients of at least five years' tanding, and whose average age was 23·4 years, ound arterio-sclerosis in the arge vessels of the lower xtremities in 18. Similar esults were obtained by White nd Hunt who demonstrated y X ray degenerative changes n the arteries of the legs in out of 48 children examined. he average age of the affected hildren was 15 8 years, and in hem the disease had been resent for an average of 6·3 ears.

Fig. 3 (Case 3).

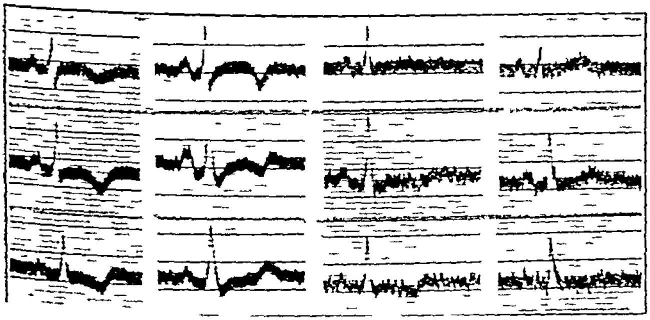


2 days. 1 week. 3 weeks. 7 weeks.

Female diabetic, aged 19. First ECG taken before treatment; note inverted T-waves. Successive records show gradual restoration of T-waves to normal form and direction in all leads after seven weeks of treatment.

There is no lack of evidence hat the coronary arteries are ften involved in degenerative processes in the course of liabetes. Indeed, the frequency with which angina pectoris and coronary thrombosis occur in diabetes is a commonplace observation. Levine (1922) found that 7 per cent. of patients with angina pectoris had previously well-defined diabetes, while in his study (1929) of 145 patients suffering from coronary thrombosis, he found glycosuria or a conclusive history of diabetes in no fewer than 23·7 per cent. In these circumstances, and recalling the early age at which advanced arterial changes have been recorded, myocardial damage might well be expected even in young diabetics and in those free from cardiac pain. Joslin (1930), writing of arterio-sclerosis in the youthful diabetic, quotes the case of a girl in her early twenties who, after a week's premonitory symptoms complained suddenly of "pain in the heart" and died within five minutes. He further refers to two male diabetics aged 30 and 33 who died of coronary thrombosis and angina, the diagnosis in both cases being confirmed by autopsy.

Fig. 4 (Case 11).

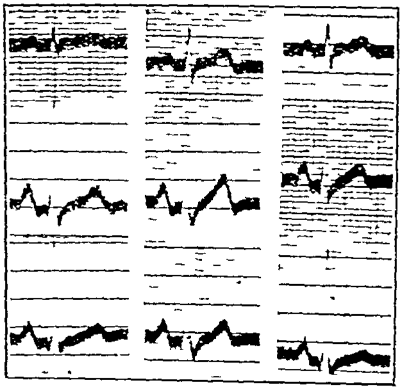


4 days. 3 weeks 15 weeks.

Female diabetic, aged 39. First ECG taken before treatment shows concise inversion of T-waves, their form in leads I. and II. suggesting "coronary" T-waves. Later records during treatment show gradual reversion to normal after 15 weeks.

The normal heart muscle stores glycogen, and according to Starling this substance is specially abundant in the conducting tissues. It seems possible that this fact may be connected with the immunity of the diabetics studied in this series from defects of conduction. That the profound disturbances of metabolism occurring in diabetes seriously involve the heart muscle was shown by Cruickshank and Patterson who demonstrated that the diabetic heart only utilises half as much glycogen per gramme per hour as the normal. It might therefore be expected that gross perversions of the normal chemical and electrical cycles taking place with each heart beat might occur even in diabetics having little or no general or coronary arterial disease. That grave disturbances of myocardial function do occasionally result from interference with carbohydrate metabolism has been shown by the studies of Hetényi, of Modern, and of Turner, who have recorded the occurrence of anginal pain as a result of hypoglycæmia in the course of treatment by insulin. Under the term "insulin angina" Parsonnet and Hyman have described the onset of cardiac infarction as an immediate sequel to insulin therapy in seven patients. The fact that in four of these the blood-sugar did not fall below the usually accepted margin of safety shows that hypoglycæmic shock was not the cause of

Fig. 5 (Case 14).



5 weeks. 10 weeks.

Male diabetic, aged 55. First ECG taken before treatment. After five weeks treatment the amplitude of the T-waves is increased in all leads. A lessened amplitude after ten weeks may be related to the action of insulin.

death. Apart from the production of anginal symptoms, there seems no doubt from the experience of these and other workers that heart failure also may be precipitated and accelerated in diabetics with myocardial disease by the use of insulin.

THE CAUSE OF ELECTROCARDIOGRAPHIC CHANGES.

It is seen from the foregoing analysis that the electrocardiographic abnormalities so frequently observed in severe diabetes are by no means constant. They are found in some patients and not in others, although clinically and biochemically both groups may be comparable. Disturbances of the Q R S and T deflections may be pronounced or very slight. Moreover, such alterations may rapidly return to normal during treatment or progressive changes may continue for some weeks or months. For changes so variable in nature, degree, and persistence, no single chemical or structural process is likely to be responsible. Some probable and possible causes are considered below.

Coronary sclerosis.—The clinical evidence for an increased incidence of coronary sclerosis in diabetes has already been discussed. Pathological studies have also gone to prove this association. For example, Blotner in a series of 77 hearts from patients dying of diabetes, found advanced disease of the coronary arteries in 45 per cent., as contrasted with a 21 per cent. incidence among 450 non-diabetic hearts. He also observed that cardiac infarction had been the cause of death in 10 per cent. of these fatal cases of diabetes. Obviously, in many diabetics of long-standing, and especially in those past middle life, there is established thickening of the coronary arteries often with irreversible intimal degeneration, and there can be no doubt that such changes with the consequent ischæmic myocardial fibrosis may account for gross and persisting electrocardiographic abnormalities.

Coronary intimal fatty deposition.—That transient intimal deposition of fat may occur in children and young adults is well known. In a discussion of this occurrence, Aschoff remarks that the "process depends purely upon the deposition of cholesterol esters." He quotes Mönckeberg, who in autopsies on 79 healthy soldiers under the age of 30 years, found aortic intimal fatty change in 57. It is held that while this intimal change of the "ascending period" of the vascular system may retrogress, the involution of a senescent atheromatous patch is absolutely excluded. In support of the view that an excessive concentration of lipoids, particularly cholesterol esters, is responsible for this intimal fatty deposition, is the well-known experimental work of Anitschkow and Chalatow on rabbits.

Studies of the cholesterol content of the blood show that this substance is frequently present in excess in diabetics. This has been shown by White and Hunt in a study of diabetic children, and by Gray in a large series of adult diabetics. Nor is the excess of cholesterol confined to the blood alone, for it has been shown to be present in unusual amount in the aorta and peripheral arteries in diabetics. Labbé, Nepveux, and Heitz found the increase to be 60 per cent. in the aorta and approximately six-fold in the tibial arteries. Since the lipoid concentration of the blood tends to be greater in severe diabetes the liability in the latter condition to fatty intimal deposition should be greater. The influence of hypercholesterolæmia in producing arterial damage remains questionable in view of the fact that the pronounced cholesterolæmias of jaundice and nephrosis are unaccompanied by arterial change. However, such cases are not strictly comparable with high-grade diabetics who have in addition a severe ketosis.

While electrocardiographic abnormalities that change within a day or two of the disappearance of hyperglycæmia and acetonuria might scarcely be ascribed to the retrogression of a fatty intimal change in a coronary artery, it is possible that this process accounts for the slow disappearance of gross abnormalities (Figs. 3 and 4) and for the gradual abolition of slurring in the Q R S complexes.

Abnormal metabolic products.—It is tempting to believe that the flattening or inversion of the T-waves in diabetes is due to the circulation of some toxic body or abnormal metabolic product in the blood. This possibility was discussed by Hepburn and Graham, who remarked that such electrocardiographic changes were not found in the few cases of "severe acidosis" studied by them, while many diabetics with considerable hyperglycæmia had normal electrocardiograms. They further concluded that hyperglycæmia and the products of perverted metabolism are not the cause of the abnormal electrocardiogram. Evidence on this matter has, from a different angle, been brought by Taterka, who has traced the electrocardiographic changes occurring in diabetic coma. His records were taken immediatel after the institution of insulin and other treatment He found a general lowering of all excursions particularly of the T-wave, which was frequentl diphasic or completely negative. These change disappeared after recovery, even though high insuli administration was being continued. This fac and the usual latency in the appearance of th electrocardiographic changes produced by insuli therapy apart from coma led Taterka to believ that the abnormal electrocardiograms could n have been due to the administration of insuli but that a toxic myocardial damage due to acidos must have been the cause. He states that comparab changes may be found in some infective diseases.

It has been shown by Dodds and Robertson th the theories of ketosis and acidosis are inadequa to explain the occurrence of coma in diabetes, sin many non-comatose patients were found to have higher aceto-acetic acid content than those in con A persistently falling blood pressure was found precede death in coma. The present investigations into myocardial function in severe diabetes and those of Taterka relating to coma lend support to the view that circulatory failure is at least a contributory cause of death in many comatose diabetics.

Defective nutrition of the myocardium.—An acute deficiency in the blood-supply to the myocardium very commonly gives rise to anginal pain. This pain is generally held to be a consequence of myocardial anoxæmia, but there is evidence that it may alternatively result from reduction in the supply of sugar to the heart, as witness the records already referred to above (Hetényi; Modern; Parsonnet and Hyman; Turner) of angina pectoris precipitated by the use of insulin whether in normal or excessive amounts. Since deprivation of oxygen or of sugar may precipitate identical symptoms, there seems, by analogy, no reason to believe that they may not cause similar electrocardiographic changes. Acute anoxæmia has been shown by Ward and Wright to cause reduction, abolition, or inversion of the T-wave in lead II., while comparable changes have been recorded by Greene and Gilbert in chronic anoxæmia. It seems, therefore, not unreasonable to infer that the changes in the T-wave may be due to the reduction in the gar-utilisation of the heart, that has been shown occur in diabetes (Cruickshank and Patterson).

Such a mechanism might account for changes which e only completely rectified after some weeks of abilisation (Figs. 3, 4, 5), as well as for those which sappear more rapidly (Fig. 2). The form of the -wave deviations in Cases 3 (Fig. 3) and 11 (Fig. 4) e of significance in this connexion. In both of these atients the T-wave was strikingly affected, and in ach case there was either flattening or inversion t all leads. Such an effect does not suggest a ronary origin, for, as Parkinson and Bedford have own. where depression of the R-T interval or -wave in lead I. is the sequel to coronary obstruction, e change, if any, in lead III. must be in the direction f elevation. The T-wave deformities in the diabetic ggest rather an intimate parenchymatous change. he rectification of such changes of long standing ight well take some weeks of dietetic and insulin reatment. A parallel may be observed in the yxœdematous patient who commonly shows inversion of the T-wave in all leads. These electrocardiographic anomalies, like those of the diabetic, lo not suggest a coronary basis, nor is arterio-scelerosis he rule in myxœdema. Treatment by thyroid medication will, after some weeks or months, reproduce a normal electrocardiogram in myxœdema, just as appropriate treatment in the diabetic soon restores the normal nutrition and activity of the myocardium, thereby restoring the normal electrocardiogram.

It is profitable also in this connexion to compare the metabolic and electrocardiographic changes observed in hyperglycæmia with those of hypoglycæmia. These two conditions are the extremes of the blood-sugar scale ; in most metabolic spheres they offer a sharp contrast, and yet the effect of both is a deficiency in the utilisation of carbohydrate. When there is sudden hypoglycæmia after previous prolonged treatment with insulin the tissues are not supplied with sufficient sugar for their needs, while in hyperglycæmia a glut of sugar is generally accompanied by an inability of the tissues to utilise it. Deficient utilisation of sugar is thus a feature of both conditions. It might therefore be expected that hypoglycæmia and hyperglycæmia would be attended by the same, if any, alterations in the curves of the electrocardiogram. This is seen to be the case. The studies of Stepp and Parade. Weichmann, and of Middleton and Oatway, to which reference has already been made, have demonstrated the depression of the T-waves in hypoglycæmia. The present observations recorded above show that in severe untreated diabetes there is also a flattening of the T-waves which become larger as treatment progresses. The effect of insulin in flattening the T-waves in the electrocardiogram has been already referred to in connexion with the present study. Several patients showed an initial increase in the amplitude of the T-waves, which was followed after some weeks of insulin therapy by a reversion to the lesser amplitude (Fig. 5).

SUMMARY.

1. Successive electrocardiograms were taken during treatment in 20 diabetics of all ages. These were at first at intervals of a few days, and later of weeks and months.

2. The tabulated results showed that the most pronounced changes occurred in patients below the age of 40, the T-waves being commonly flattened in leads I. and II., and often diphasic in lead III. Increasing amplitude of the T-waves in leads I. and II., and the substitution of an upright for a diphasic T-wave in lead III. were the effects most frequently observed during treatment. In two patients inversion of the T-wave in all leads was recorded at the outset. All of these changes disappeared progressively during treatment. whether by diet alone or by diet and insulin. The most uniform change and restoration was observed in lead II., while the T-wave in lead III. was more easily influenced by treatment and less stable in its form and direction.

3. Other occasional electrocardiographic changes occurring during treatment were progressive diminution of the P-wave and progressive lessening of slurring in the Q R S complexes.

4. The causal factors underlying the changes described were considered under the following structural and metabolic heads: (*a*) coronary sclerosis ; (*b*) coronary intimal fatty deposition ; (*c*) abnormal metabolic products ; (*d*) defective nutrition of the myocardium.

5. It was concluded that the electrocardiographic changes produced by diabetes represent mainly a parenchymatous damage to the heart resulting from defective nutrition. Coronary disease, whether sclerotic and permanent or of an early reversible fatty type, probably plays a subsidiary rôle in the production *of abnormal electrocardiograms.*

WOLVERHAMPTON CONTRIBUTORY SCHEME.—The contributory scheme of Wolverhampton Royal Hospital, which came into operation in October last, is already an assured success. It has been joined by 790 firms within its orbit, and in addition to the work of many district committees, 1400 persons are paying their contributions direct. The 3000 miners employed by the West Cannock collieries have decided to join.

JERUSALEM OPHTHALMIC HOSPITAL.—The ophthalmic hospital in Jerusalem, maintained by the British Realm of the Order of St. John, is being connected by a subway with the recently opened annexe. The annexe is lower down the main road between Jerusalem and Bethlehem than the main building, and traffic has increased so greatly that patients can no longer pass in safety from the one to the other. The work is now approaching completion.

STAPHYLOCOCCAL TOXIN.

By P. N. Panton, M.B. Camb.,
DIRECTOR OF THE HALE CLINICAL LABORATORIES, LONDON HOSPITAL;

AND

[illegible] O. Valentine, M.R.C.P. Lond.,
ASSISTANT DIRECTOR OF THE LABORATORIES.

The hæmolytic and leucocidal actions of staphylococcal toxin have been recognised for many years. Denys and Van de Velde[1] writing in 1895 described the destructive effect upon the leucocytes in the pleural cavities of rabbits following the injection of staphylococci, as well as the appearance of anti-leucocidin in the serum of immunised rabbits. The hæmolytic action of the cocci on blood-plates was noted by Kraus[2] in 1900, and in 1922 an important paper on the subject was published by Julianelle,[3] who demonstrated that the hæmolytic titre did not correspond either to pathogenicity or to leucocidin production. More recently Burnet[4] has added to our knowledge of the toxins and in particular to their mode of production in vitro. Parker Weld and Gunther[5] have described methods of separating the different components of the toxin.

The present paper deals with an investigation, both quantitative and qualitative, of the toxins obtained from 22 strains of staphylococci derived from a variety of human lesions. Our object has been to examine the relative importance of the different toxin constituents in human pathology.

The toxic properties examined were the following: hæmolytic, leucocidal, necrosing, and lethal.

TECHNIQUE AND RESULTS.

1. *Toxin preparation.*—This was obtained by Burnet's method and as previously described by us.[6] After final sterilisation through a Seitz filter the pH was brought to 7·0–7·2, a few drops of chloroform were added, and the surface of the filtrate covered with a layer of sterile liquid paraffin.

2. *Hæmolysin tests.*—Three tubes were put up for each filtrate, giving final dilutions of 1 : 50, 1 : 200, and 1 : 800. Washed rabbit cells were used in final 1 per cent. dilution. After mixing, the tubes were left in the incubator for one hour, reshaken, left on ice over night and read next morning.

3. *Necrosis of rabbit's skin.*—Intradermal doses of 0·2 c.cm. were given. Strongly hæmolytic filtrates used in 1 : 20 dilution commonly gave an area of necrosis 1·5 to 2 cm. in diameter, and this was taken to indicate a strong necrotoxin. Feebly hæmolytic filtrates were used in 1 : 5 and 1 : 20 dilutions, the former being usually feebly positive and the latter negative, indicating a weak necrotoxin. When the 1 : 5 dilution was negative a subsequent test was made with undiluted toxin. Fresh rabbits were always taken and up to six filtrates were tested simultaneously on the same animal. We believe that the results indicate adequately whether a weak or strong necrotoxin was present.

4. *Lethal action.*—This was investigated with four toxins only, Nos. 2, 3, 4, and 6. Young rabbits each weighing 1 kg. were used and a preliminary injection of 0·5 c.cm. was made into a vein. If death did not occur within a short period, further injections were made.

5. *Leucocidin.*—Human blood-cells obtained by venepuncture were washed in saline, a narrow centrifuge tube being used for the final washing in order to concentrate the leucocytes. The toxin, adjusted if necessary to pH 7–7·2, was diluted with saline to 1 : 2 and 1 : 8. Equal volumes of cells and filtrate were incubated for one hour in a Wright's pipette. The contents, after a thorough washing in and out of the pipette, were mixed in the proportions of 2 volumes of the toxin cell mixture with 1 volume of fresh human serum and 1 volume of a staphylococcal suspension. After 20 minutes' incubation the contents were again washed out, the drop thoroughly stirred with a platinum loop, and a film made from a loopful of the mixture and stained with Leishman. The addition of the phagocytic mixture was continued because it provided an additional functional test for the phagocytes and because it was found that this extra dilution of the cells led to more satisfactory films. The use of the platinum loop was adopted because the neutrophils tended to form small clumps, and it was felt that the loop would demonstrate the presence of these clumps more certainly than the usual method of drawing out a blood-film. With some filtrate mixtures after incubation, small masses tending to block the pipette were observed. These clots were caught whenever possible and rubbed out into films for examination.

In the control films many phagocytes were present, often in clumps. With a strong leucocidin (marked A in the Table) all the phagocytes were destroyed in both the dilutions 1 : 4 and 1 : 16 which were employed for the routine test. Well-stained lymphocytes were present. Such toxins usually produced clots, films of which showed masses of almost homogeneous basophil cell debris entangling normal lymphocytes. If this phenomenon occurs in vivo, it supplies a possible explanation of the septic emboli so commonly associated with staphylococcal septicæmia. Filtrates marked C in the Table appear to have no destructive action on the leucocytes in either dilution. B indicates a weak leucocidin with partial or almost complete destruction at 1 : 4 and very little action at 1 : 16. B filtrates sometimes produced clots which were found to contain many intact polymorphonuclears. The red cells, except in the case of one toxin, No. 7, were unaffected.

The Table indicates the amount of each type of toxin in the various filtrates: A represents a strong toxin; B a feeble one; and C almost complete absence of the toxin. In the fourth column an attempt is made to indicate in a similar manne the severity of the human lesion from which th strain of cocci was obtained: A represents a sever lesion such as osteomyelitis or large carbuncle, an A+ a case in which there was evidence of pyæmia B indicates a small local lesion such as a boil or stye and C a purely superficial infection such as sycosi barbæ.

D* = diabetes.

Analysis of the Table shows that the hæmolysin d necrotoxin vary together on the whole, but that ght discrepancies may occur, as with Nos. 17 and 22. th of these gave weak hæmolysin, but the necrotoxin d to be labelled A, though the reactions were finitely feebler than the majority in this class. ese slight differences tend to support Parker Weld d Gunther in their contention that the hæmolysin d necrotoxin are distinct.

FOUR GROUPS OF STRAINS.

Comparison of the hæmolysin and leucocidin rmits a division of the strains investigated into ur groups:—

1. Those with high leucocidin and low hæmolysin.
2. Those with high leucocidin and high hæmolysin.
3. Those with low leucocidin and high hæmolysin.
4. Those with low leucocidin and low hæmolysin.

is advantageous to compare these groups with the pes of human lesions from which the strains were rived.

Group 1 consists of seven strains (Nos. 3, 4, 9, 11, 4, 17, 22) with strong leucocidin and weak hæmolysin. ll these strains were obtained from severe lesions, e only exception being No. 17, which was grown from small stye, following a carbuncle from which No. 3 as obtained, and it is to be presumed that the two rains were identical. All the four strains from æmic cases fall in this group and include two rains from rapidly fatal cases of carbuncle of the p. The association therefore of this class of toxin ith virulent disease in man is remarkably constant.

Group 2 comprises three strains (Nos. 1, 8, 16) ch both in leucocidin and hæmolysin. Two were erived from a common, small single boil, and one om a small carbuncle, of short duration, which ielded rapidly to treatment. The few strains of his group in our Table may be due to the fact that hese were the only cultures examined from this ommon and perhaps most typical staphylococcal esion in man.

Group 3.—Strains with weak leucocidin and strong æmolysin (Nos. 2, 6, 7, 10D, 12, 15, 18, 20, 21). These strains were obtained from lesions of very ifferent severity but some classification is possible. The most definite finding is that all the sycosis cases all within this group—namely, 2, 6, 10D, 18. No. 7 may well be a secondary infection; No. 15 came from a case of acute osteomyelitis which cleared up rapidly after operation and without complication. No. 21 was obtained from a baby of 14 days with a strong suspicion of injury and presumably poor resistance. Nos. 12 and 20 both came from carbuncles in elderly diabetics.

Group 4.—Strains weak both in leucocidin and hæmolysin (Nos. 5, 10P, 15, 19) have some clinical evidence of a saprophytic origin; 10P grew in pale colonies and was isolated from strain 10D which yielded a strong hæmolysin. Nos. 15 and 19 both came from infected wounds, one of the hand, the other of the thorax. No. 5 strain is unique in our experience in that it produces no hæmolysin at all and no detectable leucocidin. It was derived from an osteomyelitis lesion in a child of 3 years. It is difficult to account for the appearance of this strain and its inclusion in this group. A streptococcus was subsequently isolated from the pus of the case, but the staphylococcus was obtained twice from earlier specimens in apparently pure culture.

The lethal action for rabbits was tested in the case of four toxins only. Nos. 6 and 2 were chosen as being strongly hæmolytic and feebly leucocidal, Nos. 4 and 3 as being of the reverse order; 0·5 c.cm. of the hæmolytic toxin No. 6 was given to two rabbits, the first died in three minutes, the second showed symptoms, but recovered and was given a further 1 c.cm. two hours later. Death was almost instantaneous. The other hæmolytic toxin No. 2 killed a rabbit in two minutes. Leucocidal toxin No. 4 was given to two rabbits in doses of 0·5 c.cm., followed two hours later by 1 c.cm. and 30 minutes later by a second 1 c.cm., without effect. Similarly toxin No. 3 showed no lethal action.

It appears therefore that the lethal action of a toxin for rabbits runs parallel with the necrosing effect on the rabbit's skin and the hæmolytic titre for rabbit red cells, but is distinct from the leucocidal action on human white cells.

Cultural characters.—The separation of 22 strains of staphylococci into four groups on the basis of toxin production suggested the possibility that cultural differences might be detected for the groups. The full cultural characters of 16 strains were investigated. In the fermentation reactions of the 13 carbohydrates selected all showed complete uniformity. A few strains acidified but failed to clot milk, and three strains (Nos. 7, 8, and 18) failed to liquefy gelatin. There was thus no association between cultural characters and toxin production. The peculiar strain No. 5 which yielded no toxin gave typical cultural reactions throughout.

DISCUSSION.

Antitoxin production.—In a recent paper with Mr. V. W. Dix the use of an antitoxic serum prepared for us by Dr. G. F. Petrie was described. This serum was derived from a horse inoculated with a single strain toxin of high hæmolytic titre. It was shown to have the power of neutralising both the hæmolytic and necrosing properties of the toxin. The toxin was that derived from strain No. 1 in the Table, and was subsequently found to have a high leucocidal titre also. Titration of the concentrated antiserum against normal horse serum showed an antileucotoxic power of 20 to 1. The selection of this toxin for immunisation was thus, in part, a matter of chance. It is, at least, suggested that the most important toxic fraction in severe human lesions is the leucocidal, and it is possible that a more potent serum might be obtained from the use of a Group 1 rather than a Group 2 toxin.

In our description of the toxic action upon the leucocytes we have suggested that the tough macroscopic clots found in vitro may be a source of pyæmic emboli in vivo. Dr. Petrie's antitoxic serum seemed most efficacious in the pyæmic cases and we noted at the time the complete cessation of metastatic abscess in all the cases so treated.

Constancy of toxin production.—The 22 staphylococcal strains have been divided into groups on the basis of the proportional production of hæmolysin, with which are associated necrotoxin and lethal toxin, and of leucocidin. Only four main divisions are possible and all are represented in our strains. It can be said therefore that the staphylococcus may put out much or little hæmolysin or leucotoxin or both, and any classification on these lines would be without meaning unless these outputs are *constant* for the strain. We believe that toxin production by the strain is constant within such limits as we have been able to examine them. The majority of these strains have been isolated for some months, from many of them fresh toxins have been periodically prepared on different occasions and no serious alteration in the

STAPHYLOCOCCAL TOXIN.

By P. N. Panton, M.B. Camb.,

F. C. O. Valentine, M.R.C.P. Lond.,
ASSISTANT DIRECTOR OF THE LABORATORIES.

The hæmolytic and leucocidal actions of staphylococcal toxin have been recognised for many years. Denys and Van de Velde[1] writing in 1895 described the destructive effect upon the leucocytes in the pleural cavities of rabbits following the injection of *staphylococci*, as well as the appearance of antileucocidin in the serum of immunised rabbits. The hæmolytic action of the cocci on blood-plates was noted by Kraus[2] in 1900, and in 1922 an important paper on the subject was published by Julianelle,[3] who demonstrated that the hæmolytic titre did not correspond either to pathogenicity or to leucocidin production. More recently Burnet[4] has added to our knowledge of the toxins and in particular to their mode of production in vitro. Parker Weld and Gunther[5] have described methods of separating the different components of the toxin.

The present paper deals with an investigation, both quantitative and qualitative, of the toxins obtained from 22 strains of staphylococci derived from a variety of human lesions. Our object has been to examine the relative importance of the different toxin constituents in human pathology.

The toxic properties examined were the following: hæmolytic, leucocidal, necrosing, and lethal.

TECHNIQUE AND RESULTS.

1. *Toxin preparation.*—This was obtained by Burnet's method and as previously described by us.[6] After final sterilisation through a Seitz filter the pH was brought to 7·0–7·2, a few drops of chloroform were added, and the surface of the filtrate covered with a layer of sterile liquid paraffin.

2. *Hæmolysin tests.*—Three tubes were put up for each filtrate, giving final dilutions of 1 : 50, 1 : 200, and 1 : 800. Washed rabbit cells were used in final 1 per cent. dilution. After mixing, the tubes were left in the incubator for one hour, reshaken, left on ice over night and read next morning.

3. *Necrosis of rabbit's skin.*—Intradermal doses of 0·2 c.cm. were given. Strongly hæmolytic filtrates used in 1 : 20 dilution commonly gave an area of necrosis 1·5 to 2 cm. in diameter, and this was taken to indicate a strong necrotoxin. Feebly hæmolytic filtrates were used in 1 : 5 and 1 : 20 dilutions, the former being usually feebly positive and the latter negative, indicating a weak necrotoxin. When the 1 : 5 dilution was negative a subsequent test was made with undiluted toxin. Fresh rabbits were always taken and up to six filtrates were tested simultaneously on the same animal. We believe that the results indicate adequately whether a weak or strong necrotoxin was present.

4. *Lethal action.*—This was investigated with four toxins only, Nos. 2, 3, 4, and 6. Young rabbits each weighing 1 kg. were used and a preliminary injection of 0·5 c.cm. was made into a vein. If death did not occur within a short period, further injections were made.

5. *Leucocidin.*—Human blood-cells obtained by venepuncture were washed in saline, a narrow centrifuge tube being used for the final washing in order to concentrate the leucocytes. The toxin, adjusted if necessary to pH 7–7·2. was diluted with saline to 1 : 2 and 1 : 8. Equal volumes of cells and filtrate were incubated for one hour in a Wright's pipette. The contents, after a thorough washing in and out of the pipette, were mixed in the proportions of 2 volumes of the toxin cell mixture with 1 volume of fresh human serum and 1 volume of a staphylococcal suspension. After 20 minutes' incubation the contents were again washed out, the drop thoroughly stirred with a platinum loop, and a film made from a loopful of the mixture and stained with Leishman. The addition of the phagocytic mixture was continued because it provided an additional functional test for the phagocytes and because it was found that this extra dilution of the cells led to more satisfactory films. The use of the platinum loop was adopted because the neutrophils tended to form small clumps, and it was felt that the loop would demonstrate the presence of these clumps more certainly than the usual method of drawing out a blood-film. With some filtrate mixtures after incubation, small masses tending to block the pipette were observed. These clots were caught whenever possible and rubbed out into films for examination.

In the control films many phagocytes were present, often in clumps. With a strong leucocidin (marked A in the Table) all the phagocytes were destroyed in both the dilution 1 : 4 and 1 : 16 which were employed for the routine test Well-stained lymphocytes were present. Such toxin usually produced clots, films of which showed masses almost homogeneous basophil cell debris entangling norm lymphocytes. If this phenomenon occurs in vivo, i supplies a possible explanation of the septic emboli s commonly associated with staphylococcal septicæmi Filtrates marked C in the Table appear to have r destructive action on the leucocytes in either dilution. *B indicates a weak leucocidin* with partial or almost complete destruction at 1 : 4 and very little action at 1 : 16. B filtrates sometimes produced clots which were found to contain many intact polymorphonuclears. The red cells, except in the case of one toxin, No. 7, were unaffected.

The Table indicates the amount of each type of toxin in the various filtrates: A represents a strong toxin; B a feeble one; and C almost complete absence of the toxin. In the fourth column an attempt is made to indicate in a similar manner the severity of the human lesion from which the strain of cocci was obtained: A represents a severe lesion such as osteomyelitis or large carbuncle, and A+ a case in which there was evidence of pyæmia; B indicates a small local lesion such as a boil or stye; and C a purely superficial infection such as sycosis barbæ.

Strain.	Hæmolysin.	Necrotoxin.	Leucocidin.	—	Human lesion.			—
					Sex.	Age.	D.*	
1	A	A	A	B	M.	32	–	Boil on buttock.
2	A	A	B	C	M.	30	–	Sycosis barbæ.
3	B	B	A	A	F.	46	+	Severe carbuncle of neck.
4	B	B	A	A+	F.	13	–	Fatal infection of lip
5	C	C	C	A	M.	4	–	Osteomyelitis of tibia
6	A	A	C	C	M.	2	–	Skin eruption on face
7	A	A	C	B	M.	52		Prostatitis.
8	A	A	A	B	M.	19	–	Small carbuncle of wrist.
9	B	B	A	A	M.	21	–	Severe carbuncle of neck.
10D	A	A	B	C	M.	35	–	Sycosis barbæ of 15 years' history.
10P	C	C	C	C				
11	B	B	A	A+	M.	17	–	Three years' pyæmia following bone infection.
12	A	A	B	A	F.	55	+	Carbuncle: septicæmia two years before.
13	B	B	B	B	F.	19	–	Severe infected hand.
14	B	B	A	A+	F.	15	–	Osteomyelitis of humerus and empyema.
15	A	A	C	A	M.	5	–	Acute osteomyelitis with rapid improvement.
16	A	A	A	B	M.	19	+	Nasal furuncle following many small infections.
17	B	A	A	B	F.	46	+	Stye following carbuncle in Case 3.
18	A	A	C	C	F.	28	–	Sycotic condition on leg.
19	B	B	B	A	M.	13	–	Empyema following wound of thorax.
20	A	A	B	A	M.	65	+	Severe carbuncle.
21	A	A	B	A	M.	$\frac{14}{365}$	–	Fatal abscess of back, possibly after injury.
22	B	A	A	A+	F.	21	–	Fatal infection of lip.

D* = diabetes.

EMORRHAGIC PURPURA FOLLOWING SCARLET FEVER.

REPORT OF TWO CASES IN ONE FAMILY.
